Chapter 1

Introduction

After the triumph of the Standard Model in the seventies, many theoretical physicist shifted their attention towards the understanding of the dynamics of strongly coupled quantum field theories.

In that period, in fact, quantum field theories were properly understood only by using perturbation theory, which is only applicable if the theory is weakly coupled such as QED or QCD at high energies. However, QCD is strongly coupled at energies lower than a few GeVs, thus making perturbative methods unavailable in this regime.

In this context, dualities between theories at strong and weak coupling gained a lot of attention because they can be used to compute physical quantities of strongly coupled theories in the weakly-coupled theory through well-understood perturbative methods.

Even though the Standard Model has predicted many phenomenas with great accuracy, it is believed that it is not able to describe the physical world for all the energies below the Planck scale. If one would assume that this is not true, the Standard Model has some features that differ from what physicists expect from a theory valid at such high energies. For example, some parameters such as the Higgs mass would require a fine tuning of the initial value that seems oddly unnatural for a theory valid until the Planck scale. Such fine tuning is required since the Higgs mass receives quadratic corrections. This is called usually referred as the *hierarchy problem*.

One of the possible solutions to this problem is supersymmetry, which is a symmetry between bosons and fermions. For each particle, there exists a supersymmetric partner with different spin such that every boson has a fermionic partner and vice versa. The presence of particles with different spin but identical quantum numbers removes all the quadratic corrections because loop contributions from bosons and fermions cancel each other out and only logarithmic corrections remain.

Moreover, supersymmetry theories posses many other useful renormalization properties such that they are easier to analyse with respect to non-supersymmetric

theories.

The first example of strong-weak duality is the electric-magnetic duality of Maxwell's equations discovered by Dirac in 1931, which consists in the invariance of the equations of motion under the exchange of the electric and magnetic field. In the presence of charges, electric and magnetic charges are exchanged too. For a quantum system to be invariant under such duality, electric and magnetic charges need to be inversely proportional to each other. Dirac's quantization condition for particles that possess either electric or magnetic charge reads $eg = 2n\pi\hbar$, where e is the electric charge and g the magnetic charge.

A generalization of Dirac's electric-magnetic duality is the Montonen-Olive duality. It states that a supersymmetric $\mathcal{N} = 4$ quantum field theory in four dimensions with gauge group G is equivalent to another theory with gauge group \tilde{G} and with complexified gauge coupling $\tau' = -\frac{1}{\tau}$ and with electric and magnetic degrees of freedom exchanged. The dual gauge group G' in some cases is different from the gauge group G of the original theory.

Another important strong-weak duality is the AdS/CFT correspondence. It is a duality between a gravitational theory in an Anti-deSitter space (AdS) and a conformal gauge theory (CFT) which lives on the boundary of the AdS space. It was first conjectured by Maldacena [1] between II_B string theory on $AdS_5 \times S^5$ and a $\mathcal{N} = 4$ Super Yang-Mills theory in four dimensions. It is a realization of the holographic principle, which states that gravitational theories have the same number of degrees of freedom as gauge theories in a lower number of dimensions. As we anticipated, the correspondence can be used to map observables in the strongly coupled field theory to observables in the weakly coupled gravitational theory in Anti-deSitter. It is now one of the more active areas of research and it was generalized to Anti-deSitter spaces in different dimensions and to non-conformal field theories by considering spacetime configurations that are only asymptotically Anti-deSitter. As a result, the AdS/CFT correspondence is more generally called gauge/gravity duality.

Practical applications of the correspondence ranged from the calculation of the viscosity of the quark-gluon plasma to phenomenological models of high temperature superconductors in condensed matter physics. Even if these line of research are relatively new, gauge/gravity duality can provide some insights on the behavior of strongly coupled systems in other branches of physics.

Seiberg duality is a generalization of the electric-magnetic duality to four dimensional supersymmetric field theories with the minimal amount of supersymmetry. It relates the infrared behavior of two different supersymmetric theories, the electric and the magnetic theory.

The electric theory of the first Seiberg duality discovered features a $\mathcal{N} = 1$ four dimensional gauge theory with $SU(N_c)$ gauge group and with N_f superquarks

in the fundamental and antifundamental representation. The magnetic theory is a $SU(N_f - N_c)$ gauge theory with N_f fundamental and antifundamental quarks and with N_f^2 singlets fields. They are called mesons because they have the same quantum numbers of the mesons that can be constructed in the electric theory by combining a quark with an antiquark. However, in the magnetic theory they are fundamental fields and they are not composite degrees of freedom as in the electric theory.

Both the electric and magnetic theories feature a strongly-interacting superconformal fixed point for a specific range of the number of flavours and colours. The duality maps a strongly coupled theory into a weakly coupled one as the other dualities discussed above. Therefore, we can use the magnetic degrees of freedom to analyse the properties of the electric theory in the strongly coupled regime. Many generalizations of Seiberg duality exist and they can be constructed by starting with a theory with a different gauge group or by adding matter fields in other representations.

Seiberg duality was initially discovered in four dimensional field theories but just a few years later, a three dimensional analogue of Seiberg duality with $U(N_c)$ gauge group was found by Aharony.

For fifteen years it was not clear how to link dualities in four and three dimensions even if they had many similarities. A naive dimensional reduction of a theory is obtained by compactifying a direction to a circle and then ignoring the Kaluza-Klein modes associated to the compactified dimension. This kind of dimensional reduction does not preserve the duality between the electric and the magnetic theory.

However, the duality can be preserved in the reduction if we consider the effects of the finite size of the circle. In particular, there is one Kaluza-Klein instantonic state that needs to be considered in order to preserve the duality. In fact, this instanton generates a non-perturbative superpotential term that breaks the additional symmetries present in three dimensional field theories.

Flowing to low-energies, the Kaluza-Klein modes on the circle decouple and the theory exhibits an effectively three-dimensional behaviour. However, the instantonic superpotential is still present. It can be removed by performing a real mass flow by assigning to some quarks large real masses, obtaining a three dimensional duality without additional superpotential terms.

We can apply this reasoning to different four dimensional dualities. In some cases we find already known dualities, while in other situations we discover unknown three dimensional dualities. Given that most of the three dimensional dualities have been derived from four dimensional dualities, it is conjectured that this is true for every three dimensional duality.

The process of dimensional reduction is understood in field theory in most cases, but some difficulties could arise because of the strong coupling regime. However, the results obtained in this way can be checked with an independent

method which consists in the reduction of the duality directly through the partition function. The reduction process starts by calculating the superconformal index in four dimensions, for both dual theories. The index is a quantity defined for supersymmetric field theories in four dimensions with one of the directions compactified into a circle. It counts the multiplets that have a specific relation between energy and angular momentum (BPS short multiplets). After the dimensional reduction, once the Kaluza-Klein modes are integrated out these multiplets correspond to bosonic and fermionic modes on the three-sphere. As a result, the partition function on the three sphere can be obtained by considering the superconformal index in the limit of zero radius.

Mathematical identities guarantees that the indices of dual theories match.

We start the reduction by calculating the superconformal index for both dual theories and then we reduce the index to the partition function by shrinking the radius of the circle to zero. By performing a flow with large real masses assigned to some of the quarks, the instantonic superpotential disappears and we obtain a duality between three dimensional theories with the all the symmetries that were broken by the instantonic superpotential. This process can be done directly on the partition function and the result of the flow can be read easily from the partition function.

Our work focuses on the dimensional reduction of Seiberg duality with $SU(N_c)$ gauge group and with an additional chiral field in the adjoint representation by using the partition function approach discussed earlier. This duality is known in literature as the Kutasov-Schwimmer-Seiberg (KSS) duality. Its three dimensional analogue is called Kim-Park duality and it has a similar matter content to the four dimensional duality with the addition of singlet fields in the magnetic theory that have the same charges of the monopole operators of the electric theory. The electric theory of Kim-Park is either $U(N_c)$ or $SU(N_c)$ which correspond to different magnetic theories.

The dimensional reduction of the KSS duality to the Kim-Park duality with $U(N_c)$ or $SU(N_c)$ gauge groups has been performed by Nii with field theory techniques.

The scope of our work is to provide an independent check of his work by performing the dimensional reduction of KSS duality to $SU(N_c)$ Kim-Park duality on the partition function.

The advantage of this approach is that it is easier to work on the partition function rather than in field theory mostly because of the non-perturbative regime. Moreover, in field theory one has to make some assumptions that are not still completely justified, while in the partition function approach those assumptions are not needed. Whereas the reduction on the partition function to $U(N_c)$ Kim-Park duality has already been done in literature, the reduction of the $SU(N_c)$ case wasn't performed yet. Thus, our work provides an independent check of the results obtained with field theory techniques.

The identity between the electric and magnetic partition function is not yet demonstrated as a mathematical identity and it could be one of the situations where physics can unveil new non-trivial mathematical relations.

We begin our discussion in section 2 with a brief review of some of the properties of supersymmetric quantum field theories and the features of $SU(N_c)$ SQCD that will be needed in order to understand Seiberg duality. After these considerations we illustrate Seiberg and KSS duality.

In section 3 we consider the different properties of supersymmetric theories in three dimensions with respect to the four dimensional ones. Then, we introduce Aharony duality for $U(N_c)$ gauge group and Kim-Park duality for $U(N_c)$ or $SU(N_c)$ gauge groups.

In the fourth section we review the process of dimensional reduction in field theory, applying it to Seiberg duality, which results in a three dimensional duality that wasn't known before the introduction of this method. We consider also the flow to Aharony duality, obtained by gauging the baryonic symmetry. Then, we consider the reduction of KSS duality to Kim-Park with $U(N_c)$ and with $SU(N_c)$ gauge group.

In section 5 we give a brief introduction of the superconformal index, highlighting the key features that we will need in our analysis and we will also review the method of localization, which allows to compute partition functions exactly. Moreover, we give an overview of the dimensional reduction procedure on the index to the partition function.

The last section is dedicated to our work and contains the key steps of the dimensional reduction with the partition function approach. Explicit calculations can be found in the appendix.

Chapter 2

Four dimensional dualities

2.1 Introduction

Supersymmetric quantum field theories enjoy an enlarged group of symmetries compared to other field theories. Since the symmetry group is a non-trivial combination of internal and spacetime symmetries, they have many unexpected features and new techniques were found to study them. Almost all of the new tools found are available only for supersymmetric field theories, making them the theatre for many advances in physics.

A more technical introduction on supersymmetry and its representation on fields can be found in appendix A.

In this section we will analyse more advanced features of supersymmetric field theories that have been used intensively in the discovery and in the analysis of electric magnetic duality and its generalisations.

2.1.1 General renormalization properties

A remarkable feature of supersymmetry is the constraint that the additional symmetry imposes on the renormalization properties of the theories.

One of the first aspects that brought attention to supersymmetry was that divergences of loop diagrams were milder because of the cancellation between diagrams with bosons and fermions running in the loops.

Nowadays we know powerful theorems that restrict the behaviour of supersymmetric field theories under renormalization. In order to preserve supersymmetry, the renormalization process has to preserve the Hilbert space structure. For example the wave function renormalization of different *particles* inside a multiplet must be the same, otherwise the renormalized lagrangian is not supersymmetric invariant anymore.

Moreover, in the supersymmetry algebra P^2 is still a Casimir operator i.e. it commutes with every operator in the algebra: particles in the same multiplet must have the same mass. Renormalization cannot break this condition, other-

wise it would break supersymmetry.

For a *Super Yang Mills* theory with $\mathcal{N} = 1$ symmetry considerations lead to the additional requirement that gV , where g is the coupling and V is the vector superfield, cannot be renormalized.

Adding more supersymmetry the wave function renormalization of the various fields are even more constrained by symmetry. For example, for $\mathcal{N} = 4$ *SYM* the coupling constant is not renormalized at all.

Beta function for SYM and SQCD

Another nice feature of supersymmetric field theories is that some quantities can be calculated exactly. The first object of this kind that we encounter is the β -function of four dimensional $\mathcal{N} = 1$ *Super Yang Mills* theories with matter fields in representations R_i .

It is given by the exact *NSVZ β -function*

$$\beta(g) = \mu \frac{d g}{d \mu} = -\frac{g^3}{16\pi^2} \left[3 T(\text{Adj}) - \sum_i T(R_i)(1 - \gamma_i) \right] \left(1 - \frac{g^2 T(\text{Adj})}{8\pi^2} \right)^{-1} \quad (2.1)$$

where γ_i are the anomalous dimensions of the matter fields and $T(R_i)$ are the Dynkin indices¹ of their representation.

The anomalous dimensions are defined as

$$\gamma_i = -\mu \frac{d \log(Z_i)}{d \mu} \quad (2.2)$$

where Z_i is the wave function renormalization coefficient. The Dynkin indices of the gauge group $SU(N)$ for the fundamental and adjoint representation are

$$T(N) = \frac{1}{2} \quad T(\text{Adj}) = N \quad (2.3)$$

The *NSVZ β -function* was first calculated using instanton methods in [2].

2.1.2 Superpotential: holomorphy and non-renormalization

Other than renormalization constraints, supersymmetry provides non-renormalization theorems for certain objects, such as the superpotential.

In [3] it has been demonstrated that the superpotential is tree-level exact, i.e. it does not receive correction in perturbation theory. However it usually receive contributions from nonperturbative dynamics. The superpotential features this property in theories with at least four supercharges and can be demonstrated independently using perturbative calculations or its holomorphic properties.

¹The Dynkin index $T(R)$ of a representation R is defined as $\text{Tr}(T^a T^b) = T(R) \delta^{ab}$ where T^a , T^b are the generators of the algebra in the representation R .

It was first demonstrated perturbatively, using the fact that for general supersymmetric field theories, supergraph loops diagrams with n external leg yield a term that can be written in the form

$$\int d^4x_1 \dots d^4x_n d^2\theta d^2\bar{\theta} G(x_1, \dots, x_n) F_1(x_1, \theta, \bar{\theta}) \dots F_n(x_n, \theta, \bar{\theta}) \quad (2.4)$$

where F_i are given by products of superfields and their covariant derivatives and $G(x_1, \dots, x_n)$ is translationally invariant function.

The importance of this result is that all contribution from Feynman diagrams are given by a single integral over full superspace ($d^2\theta d^2\bar{\theta}$) whereas the superpotential must be written as an integral in half-superspace ($d^2\theta$ only) of chiral fields. Exploiting the fact that a product of chiral fields is a chiral field, the most general form of a superpotential is

$$W(\lambda, \Phi) = \sum_{n=1}^{\infty} \left(\int d^2\theta \lambda_n \Phi^n + \int d^2\bar{\theta} \lambda_n^\dagger \bar{\Phi}^n \right) \quad (2.5)$$

The second term of the superpotential is added in order to give a real lagrangian after the integration in superspace. From the definition, we can see that the superpotential is holomorphic in the fields and in the coupling constants.

An alternative proof of this theorem was provided by Seiberg [4] using a different approach. He noted that the coupling constants λ_n can be treated as background chiral superfields with no dynamics.

Using this observation we can assign transformation laws to the coupling constants, making the lagrangian invariant under a larger symmetry. Fields and coupling constants are charged under this symmetry and only certain combinations of them can appear in the superpotential. In addition, in a suitable weak coupling limit the effective superpotential must be identical with the tree-level one. These conditions, taken together, fix the expansion of the superpotential to the expression of the tree-level potential. A more detailed discussion can be found in [5] and [6].

2.1.3 Moduli space

The *classical moduli space* is the set of vacuum expectation values of the scalar fields that correspond to a zero of the scalar potential. The zeroes of the scalar potential can be found by solving to two different sets of equations, called *D-term* and *F-term* equations

$$\bar{F}^i(\phi) = 0 \quad D^a(\phi, \bar{\phi}) = 0 \quad (2.6)$$

F-term equations are present only if there is a superpotential while the *D-term* equations are associated to the kinetic part of the lagrangian.

If the minimum of the scalar potential is different from zero the vacuum is not supersymmetric. In this case supersymmetry is spontaneously broken. Another possible situation is that the scalar potential has no minimum at all: the theory

does not have any stable vacua.

If it is not possible to find vacuum expectation values that correspond to a zero in the scalar potential, then the theory does not possess a moduli space.

Gauge transformations should be taken into account in order to avoid redundancy in the description. The moduli space describes physically inequivalent vacua, since the mass spectrum of the theory depends on the *VEVs* of the scalar fields, which differ in every point of the moduli space.

Because of supersymmetry, radiative corrections do not lift the energy of the ground state and the vacuum remains supersymmetric. As a result, only superpotentials generated from nonperturbative dynamics can lift the moduli space. We will see examples of this phenomenon in the analysis of SQCD.

An alternative description of the space of classical *D-flat* directions is given by the space of all holomorphic gauge invariant polynomials of scalar fields modulo classical relations between them [7]. As a result, gauge invariant polynomials of operators parametrize the classical moduli space of the theory. Using this description it's easier to find the moduli space of the theory in consideration. If a superpotential is present, *F-term* equations should be imposed on the gauge invariant polynomial used to describe *D-flat* direction. We will use this convenient description in the next chapters.

Quantum moduli space

The quantum-corrected moduli space is in general different from the classical one, although there are situations in which they coincide, as we will see in the next sections.

The quantum moduli space can be found by searching for the minima of the Wilsonian low-energy effective action. In general the effects of renormalization on the Kähler potential do not modify the geometry of the moduli space.

On the other hand, non-perturbative dynamics generates in general non-trivial terms in the superpotential that modify the moduli space. The non-perturbative term in the superpotential can be found by considering the symmetries of the theory and the holomorphy of the superpotential. In most situations, they constrain its form in such a way that it can be found by using solely symmetry considerations. However, in some cases they are not enough to fix its expression and we don't have a description of the quantum moduli space.

If a non-trivial effective superpotential is generated, it will usually lift part of the moduli space or modify its geometry, removing the singular point present in the classical moduli space. The singularities in the classical moduli space are located in point of enhanced gauge symmetries or where are present massless degrees of freedom such as in the origin of the moduli space. The quantum moduli space does not have such singularities and it is in fact a smooth manifold.

2.1.4 Phases of gauge theories

The dynamics of gauge theories can be classified according to the low-energy effective potential $V(R)$ between two test charges separated by a large distance R . The possible forms of the potential, up to additive constant, are

$$\text{Coulomb} \quad V(R) \sim \frac{1}{R} \quad (2.7)$$

$$\text{free electric} \quad V(R) \sim \frac{1}{R \log(R\Lambda)} \quad (2.8)$$

$$\text{free magnetic} \quad V(R) \sim \frac{\log(R\Lambda)}{R} \quad (2.9)$$

$$\text{Higgs} \quad V(R) \sim \text{constant} \quad (2.10)$$

$$\text{confining} \quad V(R) \sim \sigma R \quad (2.11)$$

The first three phases feature massless gauge fields and their potential is $V(R) \sim g^2(R)/R$ and they differ because of the renormalization of the charge in the infrared. In the Coulomb phase, $g_{IR}^2 = \text{constant}$, while in the free abelian/non-Abelian phase the coupling constant goes to zero as $g^2(R) \sim 1/\log(R\Lambda)$. The free electric phases is possible for abelian or non-Abelian theories. In the latter case for asymptotically free theories it is necessary that the renormalization group has a non-trivial infrared fixed point. The free magnetic phases is generated by magnetic monopoles acting as source of the field. Since magnetic and electric charges are related by Dirac quantization condition, the running of the coupling constant for magnetic monopoles is the inverse of electric charges.

The situation is completely different in the last two cases. In the Higgs phase gauge fields are massive and the potential is given by a Yukawa potential, exponentially suppressed at long distances that results in a constant value. The confining phase can be described by tube of confined gauge flux between the charges which, at large distances, acts as a string with constant tension, yielding a linear potential.

2.1.5 't Hooft anomaly matching conditions

The 't Hooft anomaly matching conditions are a great tool to investigate the global symmetries of the low-energy degrees of freedom of the theory.

Let's consider an asymptotically free gauge theory with global symmetry group G . While gauge symmetries cannot be anomalous because that would spoil the unitarity of the theory, this condition does not apply to anomalies involving only global symmetries.

We can compute the triangle anomaly for the global symmetry group in the ultraviolet and we will call it A_{UV} . After weakly gauging G we introduce additional fermions that are charged only under G in order to cancel the anomaly, since now it is a gauge symmetry.

Flowing towards the infrared, the anomaly is still zero if the global symmetry

group is not broken. After constructing the low-energy effective field theory, we can calculate the triangle anomalies for the group G involving the composite low energy fields, which results in the term A_{IR} . The contribution of the additional fermions remains identical since they are massless.

$$0 = A_{IR} + A_F = A_{UV} + A_F \quad \rightarrow \quad A_{IR} = A_{UV} \quad (2.12)$$

The anomaly coefficient can be easily computed since it is proportional to the group theoretical factor

$$A = \text{Tr} (T^a \{T^b, T^c\}) \quad (2.13)$$

Summarizing the result, we found that if the global symmetry group is not broken by the strong dynamics, triangle anomalies involving only the global symmetry group should be equal in the ultraviolet and in the infrared.

We will use these anomaly matching conditions to find if two dual theories are invariant under the same global symmetries in the IR as an additional check of electric-magnetic duality.

2.2 Seiberg duality

Electric magnetic duality relates the dynamics of two different gauge theories in their infrared fixed point. Even though the dual theories have different particle content, they describe the same IR physics. Moreover, whenever one of the dual theories gets more strongly coupled, the other becomes more weakly coupled. This is particularly useful because it provides an alternative, weakly coupled description of the original theory.

2.2.1 Electric theory: $SU(N)$ SQCD with N_f flavours

We will start our analysis on electric-magnetic duality studying the first pair of theories that were discovered to be dual in [8]. We are going to analyse the properties of these theory in order to better understand the features of the duality.

The electric theory is a $SU(N_c)$ supersymmetric gauge theory with N_f massless flavours. Its anomaly-free global symmetry group is

$$SU(N_f)_L \times SU(N_f)_R \times U(1)_B \times U(1)_R \quad (2.14)$$

The axial symmetry gives rise to an anomaly through the triangular graph $U(1)_A \times SU(N_c)^2$, hence it is not a symmetry of the theory.

The classical lagrangian in superspace language is given by

$$\mathcal{L} = \tau \int d^2\theta \text{Tr}(W_\alpha W^\alpha) + \text{h.c.} + \int d^2\theta d^2\bar{\theta} (Q^i)^\dagger e^V Q_i + \int d^2\theta d^2\bar{\theta} (\tilde{Q}^{\tilde{i}})^\dagger e^{-V} \tilde{Q}_{\tilde{i}} \quad (2.15)$$

Figure 2.1: Feynman graphs contributing to the R-symmetry anomaly

Q and \tilde{Q} represent left and right quark superfield respectively. The charges of the fields are given in the table below.

	$SU(N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$
Q	N_c	N_F	1	1	$\frac{N_f - N_c}{N_f}$
\tilde{Q}	$\overline{N_c}$	1	$\overline{N_F}$	-1	$\frac{N_f - N_c}{N_f}$

(2.16)

The value of the R-charge is fixed by the triangle anomaly $SU(N_c)^2 U(1)_R$, which can be calculated by considering diagrams with two exiting gluons and the R-symmetry current inserted in the other vertex. Each fermion in the theory contributes to the anomaly which, as a result, is proportional to the R-charge of the fermions running in the loop and the Dynkin index of its representation. Requiring the anomaly to vanish, we find

$$R_{gaugino}T(\text{Ad}) + \sum_f (R_f - 1)T(r) = 0 \quad (2.17)$$

$$N_c + \frac{1}{2} 2N_f(R_Q - 1) = 0 \quad \rightarrow \quad R_Q = \frac{N_f - N_c}{N_f} \quad (2.18)$$

where we set the gaugino R-charge to 1 in order to have gluons not charged under R-symmetry.

The anomaly free condition for the R-symmetry leads to a unique set of R-charges. As a result, we found the R-charges at the superconformal infrared point of the theory.

Classical moduli space

Considering that the theory has no superpotential, the classical moduli space of the theory is given by D -terms only. They can be read from the on-shell lagrangian and are given by

$$D^a = g \left(Q^{*i} T^a Q_i - \tilde{Q}^{*i} T^a \tilde{Q}_i \right) = 0 \quad (2.19)$$

where T^a are the gauge group generators in fundamental or antifundamental representation and i is a flavour index.

After considering gauge and global symmetries, the squark $VEVs$, represented as $N_f \times N_c$ matrices, which satisfy the D-term equation are given by

- for $N_f \leq N_c$ and a_i generic

$$Q = \tilde{Q} = \begin{pmatrix} a_1 & 0 & 0 & 0 & 0 & \dots & 0 \\ 0 & a_2 & 0 & 0 & 0 & \dots & 0 \\ 0 & 0 & \ddots & 0 & \vdots & \dots & \vdots \\ 0 & 0 & 0 & a_{N_f} & 0 & \dots & 0 \end{pmatrix} \quad (2.20)$$

- for $N_f \geq N_c$ and $|a_i|^2 - |\tilde{a}_i|^2 = a$ independent of i .

$$Q = \begin{pmatrix} a_1 & 0 & 0 & 0 \\ 0 & a_2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & a_{N_c} \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{pmatrix} \quad \tilde{Q} = \begin{pmatrix} \tilde{a}_1 & 0 & 0 & 0 \\ 0 & \tilde{a}_2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \tilde{a}_{N_c} \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{pmatrix} \quad (2.21)$$

For $N_f \leq N_c$ in a generic point of the moduli space the gauge group is broken to $SU(N_c - N_f)$ while for $N_f \geq N_c$ is broken completely. The gauge group breaks through the super Higgs mechanism: every broken generator is absorbed by the associated massless vector superfield. This process gives mass to the vector superfield.² The mass of the gauge superfield is given by the VEVs of the squarks.

As we said in section 2.1.3, we can study the classical moduli space by finding holomorphic gauge invariant polynomials in the operators and modding out classical relations between them. For $N_f < N_c$ we can only construct *mesons* out of squarks

$$M_j^i = Q^i \tilde{Q}_j \quad (2.22)$$

where color indices are summed. Mesons have maximal rank because $N_f < N_c$ and there are no classical constraints to impose on them.

When $N_f \geq N_c$ the mesons cannot have maximal rank anymore, it can be at most N_c . There are additional gauge invariant operators that can be constructed: *baryons*, that are defined as

$$B_{i_1, \dots, i_{N_f - N_c}} = \epsilon_{i_1, \dots, i_{N_f - N_c}, j_1, \dots, j_{N_c}} \epsilon^{a_1, \dots, a_{N_c}} Q_{a_1}^{j_1} \dots Q_{a_{N_c}}^{j_{N_c}} \quad (2.23)$$

$$\tilde{B}^{i_1, \dots, i_{N_f - N_c}} = \epsilon^{i_1, \dots, i_{N_f - N_c}, j_1, \dots, j_{N_c}} \epsilon_{a_1, \dots, a_{N_c}} \tilde{Q}_{j_1}^{a_1} \dots \tilde{Q}_{j_{N_c}}^{a_{N_c}} \quad (2.24)$$

²Remember that massive representation of supersymmetry have twice the degrees of freedom of massless ones, because in the latter half of the supercharges are represented trivially.

Mesons and baryons can be written down using the *VEVs* we found solving the *D-term* equations (ignoring null components for baryons)

$$M = \begin{pmatrix} a_1 \tilde{a}_1 & 0 & \dots & 0 & 0 & \dots & 0 \\ 0 & a_2 \tilde{a}_2 & 0 & \dots & 0 & \dots & 0 \\ \vdots & 0 & \ddots & 0 & 0 & \dots & 0 \\ \vdots & \vdots & 0 & a_{N_c} \tilde{a}_{N_c} & 0 & \dots & 0 \\ 0 & 0 & 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \quad (2.25)$$

$$B \simeq a_1 a_2 \dots a_{N_c} \quad (2.26)$$

$$\tilde{B} \simeq \tilde{a}_1 \tilde{a}_2 \dots \tilde{a}_{N_c} \quad (2.27)$$

We can see that if the mesons have rank less than N_c , then B or \tilde{B} (or both) has to vanish and the other has rank one. If the mesons' rank is N_c both B and \tilde{B} have rank one.

There are classical constraints that should be imposed between mesons and baryons, but depend on the number of flavours. For example for $N_f = N_c$ the classical constraint is $\det(M) - B\tilde{B} = 0$.

Singularities of the moduli space can be investigated using the gauge invariant description we have just introduced. The part of the lagrangian that describes flat directions can be written in terms of mesons and baryons. The lagrangian involving mesons features a non-trivial Kähler potential that reads

$$K = 2\text{Tr} \sqrt{M^\dagger M} \quad (2.28)$$

that generates a singular metric whenever the meson matrix is not invertible. This happens when some of the VEVs are zero, i.e. in points of the moduli space of enhanced gauge symmetry. The appearance of this singularities is related to the fact that some (or all) gluons are now massless and should be included in the low-energy description.

Quantum moduli space

Quantum dynamics modifies the structure of the moduli space of the theory in a different way depending on the number of colours and flavours.

Pure SYM For pure *Super Yang Mills*, i.e. no quarks, the theory exhibit a discrete set of N_c vacua. Without quarks a non-anomalous R-symmetry cannot be found, and the R-symmetry is broken down to the discrete symmetry \mathbb{Z}_{2N_c} . Using holomorphy and symmetry arguments, the form of the non-perturbative potential can be found and it can be shown that it induces the gaugino to condensate [9], meaning that

$$\langle \lambda\lambda \rangle = -\frac{32\pi^2}{N_c} a \Lambda^3 \quad (2.29)$$

Figure 2.2: Qualitative graph of the ADS superpotential

where Λ is the dynamically generated scale of the theory defined as

$$\Lambda = \mu e^{-\frac{2\pi i \tau}{b_0}} \quad \tau = \frac{4\pi i}{g^2(\mu)} + \frac{\theta_{YM}}{2\pi} \quad b_0 = 3N_c - N_f \quad (2.30)$$

where τ is the complexified gauge coupling. $|\Lambda|$ is defined as the scale at which the coupling constant diverges.

The gaugino condensation breaks R-symmetry to \mathbb{Z}_2 and in fact there are N_c physically different vacua labeled by different phases of the gaugino condensate.

$N_f < N_c$ The quantum corrections for *SQCD* with $N_f < N_c$ flavours completely lift the moduli space through the Affleck-Dine-Seiberg (ADS) superpotential [10, 11] which reads

$$W_{eff} = (N_c - N_f) \left(\frac{\Lambda^{3N_c - N_f}}{\det M} \right)^{\frac{1}{N_c - N_f}} \quad (2.31)$$

It is the only superpotential that is compatible with the symmetries of the theory and with the other properties of the superpotential we introduced in section 2.1.2. We can see that the ADS superpotential does not exist for $N_f \geq N_c$ because the exponent diverges for $N_f = N_c$ or the determinant vanishes for $N_f \geq N_c$ because mesons do not have maximal rank. Note that this superpotential is non-perturbative and thus it is not in contrast with the renormalization theorem of section 2.1.2. The effect of this superpotential is that the theory does not have ground state. The slope of the potential goes to zero only for $\det M \rightarrow \infty$. This situation is the perfect example where, unlike the classical moduli space, quantum corrections lift completely the moduli space and the theory does not posses a vacuum anymore.

$N_f = N_c$ When the number of flavours is equal the number of colours of the theory, the classical moduli space was subject to the constraint

$$\det M - B\tilde{B} = 0 \quad (2.32)$$

In the quantum corrected moduli space mesons and baryons satisfy [12]

$$\det M - B\tilde{B} = \Lambda^{2N_c} \quad (2.33)$$

which flows to the classical constraint in the classical limit ($\Lambda \rightarrow 0$).

The effect of this relation is that the origin does not belong to the moduli space anymore and the moduli space is now smooth. For large expectation values of M , B and \tilde{B} the classical and the quantum moduli space look similar, while in the origin of the moduli space quantum corrections modify drastically the structure of the moduli space. Moreover, the subspace with B or \tilde{B} equal to zero, is not singular anymore while classically the meson matrix was constrained to have zero determinant.

The fact that the origin of moduli space is not in the quantum-corrected moduli space, implies that the global symmetry group is necessarily broken in some way, depending on the position of the moduli space

$$M_j^i = \Lambda^2 \delta_j^i \quad B = \tilde{B} = 0 \quad \rightarrow \quad SU(N_f)_V \times U(1)_B \times U(1)_R \quad (2.34)$$

$$M_j^i = 0 \quad B = -\tilde{B} = \Lambda^{N_c} \quad \rightarrow \quad SU(N_f)_L \times SU(N_f)_R \times U(1)_R \quad (2.35)$$

where $SU(N_f)_V$ is the diagonal vector subgroup.

$\mathbf{N}_f = \mathbf{N}_c + \mathbf{1}$ In the case $N_f = N_c + 1$ the classical moduli space is constrained by

$$\det M \left(\frac{1}{M} \right)_i^j - B_i \tilde{B}^j = 0 \quad M_j^i B_i = M_j^i \tilde{B}^j = 0 \quad (2.36)$$

and quantum corrections do not modify it. In the previous section we noted that the singularities in the classical moduli space are associated to the appearance of massless gluons. In the quantum picture, the interpretation of the singularities is different: they are associated with additional massless mesons and baryons. At the origin of the moduli space the theory is strongly coupled and the global symmetry (2.14) is unbroken and it can be checked using 't Hooft anomalies [12]. Far from the origin, the mesons and baryons interact with the potential

$$W = \frac{1}{\Lambda^{2N_c-1}} (M_j^i B_i \tilde{B}^j - \det M) \quad (2.37)$$

Figure 2.3: Classical and quantum 2D slice of the moduli space near the origin for $N_f = N_c$ [13]

that enforce the classical constraints (2.36) through the equations of motion. For large VEVs of the fields, mesons and baryons acquire large mass through the superpotential.

$N_f > N_c + 1$ Starting from $N_f = N_c + 2$ it is not possible to construct a physical superpotential out of gauge invariant operators, in analogy to the previous cases. The only $SU(N_f)_L \times SU(N_f)_R$ invariant superpotential that can be written is given by

$$W_{eff} \sim \det M - B_{ij} M_k^i M_l^j \tilde{B}^{kl} \quad (2.38)$$

because baryons have two flavour indices. However this superpotential does not have R-charge equal to two and if we add more flavours we should add other mesons to the superpotential. Therefore the classical moduli space is not modified by quantum corrections. As a result, near the origin the quantum corrected moduli space looks identical to the classical one. Unlike the case with $N_f = N_c + 1$ the singularities in the moduli space cannot be interpreted as massless mesons and baryons and an effective description of these operator is singular [12]. Considering that the 't Hooft anomaly matching conditions are not satisfied in the singular points it is clear that a description using mesons and baryons is not correct.

To find a description of the low-energy degrees of freedom of the theory we will use Seiberg duality, which provides an alternative description of the theory.

Conformal window The theory is not asymptotically free in the range $\frac{3}{2}N_c < N_f < 3N_c$. This can be seen by using the $NSVZ$ β function (2.3), which reads

$$\beta(g) = -\frac{g^3}{16\pi^2} \frac{3N_c - N_f + N_f \gamma(g^2)}{1 - N_c \frac{g^2}{8\pi^2}} \quad (2.39)$$

$$\gamma(g^2) = -\frac{g^2}{8\pi^2} \frac{N_c^2 - 1}{N_c} + \mathcal{O}(g^4) \quad (2.40)$$

The β function is known to have a Banks-Zaks fixed point [14] in the 't Hooft limit with $\frac{N_f}{N_c} = 3 - \epsilon$ held fixed and $\epsilon \ll 1$. However, the fixed point exists in the range of values $\frac{3}{2}N_c \geq N_f \geq 3N_c$ with N_f and N_c finite. This is possible because one loop and two loop contributions to the beta function have opposite signs. As a result, the infrared theory is a non-trivial four dimensional superconformal theory. The infrared degrees of freedom are quarks and gluons that are not confining but are interacting as massless particles. The theory is in a free non-Abelian Coulomb phase.

The fact that the theory is superconformal implies that we have further restrictions on the algebra of operators ³. Superconformal algebra imposes that the

³ R-symmetry is part of the superconformal algebra instead of being an automorphism of the algebra, as in superPoincaré algebra.

dimension of every operator satisfy this inequality involving the R-charge

$$D \geq \frac{3}{2} |R| \quad (2.41)$$

where the bound is saturated for chiral fields.

The product of two chiral operator is constrained by this fact. Consider that for two operators O_1, O_2 we have $R(O_1 O_2) = R(O_1) + R(O_2)$. Because of the bound (2.41), the scaling dimension of chiral operators is additive $D(O_1 O_2) = D(O_1) + D(O_2) = \frac{3}{2}R(O_1) + \frac{3}{2}R(O_2)$. Note that the dimension of the operator is quantum corrected, i.e. contains the anomalous dimension of the operator.

Given that the superconformal R-symmetry is not anomalous and commutes with the global symmetry group of the theory, then it must be the R-symmetry that appears in table 2.16. Because of (2.41), the gauge invariant operators we defined previously must have the following dimensions

$$D(Q\tilde{Q}) = \frac{3}{2}R(Q\tilde{Q}) = 3\frac{N_f - N_c}{N_f} \quad (2.42)$$

$$D(B) = D(\tilde{B}) = \frac{3}{2}N_c\frac{N_f - N_c}{N_c} \quad (2.43)$$

Gauge invariant operators should be in unitary representation of the superconformal algebra. Unitarity imposes that in general $D \geq 1$ and the equality holds for singlet fields. From the previous equation we can verify that $D(M) \geq 1$ for $N_f \geq \frac{3}{2}N_c$ and it becomes a free field for $N_f = \frac{3}{2}N_c$.

For fewer number of flavours, the meson field is inconsistent with the unitarity bound. The theory is conjectured to flow to a different phase.

$N_f > 3N_c$ In this range, quarks prevail on gluons and change the sign of the β function. This is caused by the *charge screening* effect of quarks, that make the coupling constant smaller at larger distances.

The theory is in a free non-Abelian electric phase. Its behavior is not well defined at high energies because of the presence of a Landau pole at $R \sim \Lambda^{-1}$, although the theory can be a good description of a low-energy limit of another theory.

2.2.2 Magnetic theory

The magnetic theory is a $SQCD$ theory with the same global symmetries as the electric theory, but with gauge group $SU(\tilde{N}_c = N_f - N_c)$. In addition there are N_f^2 color singlets, that we will call mesons, Considering that they have the same properties as the mesons we can construct in the electric theory. In the magnetic theory they are fundamental fields i.e. they are not written as gauge invariant operators from quarks. Given that they are gauge invariant, they interact only through the superpotential

$$W = M_j^i q_i \tilde{q}^j \quad (2.44)$$

where we represented dual quarks as q, \tilde{q} and mesons as M_j^i . The charges of fields of the magnetic theory are

	$SU(N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$
q	N_c	$\overline{N_F}$	1	$\frac{N_c}{N_f - N_c}$	$\frac{N_c}{N_f}$
\tilde{q}	$\overline{N_c}$	1	N_F	$-\frac{N_c}{N_f - N_c}$	$\frac{N_c}{N_f}$
M_j^i	1	N_f	$\overline{N_f}$	0	$2\frac{N_f - N_c}{N_f}$

(2.45)

Dual quarks are in opposite representations of flavour symmetries.

Mesons in the magnetic theory have the same charges of the mesons constructed from electric quarks. Baryons constructed from dual quarks have the same baryonic charge as the electric baryons and are mapped into each other by the duality. It can be demonstrated that they are proportional to each other.

Similarly to the electric theory, the R-charges can be chosen in order for the R-symmetry to be non-anomalous.

However, the R-charges can be found by imposing the duality. If we use the fact that the mesons are built from electric quarks, their R-charge is twice the R-charge of electric quarks. The R-charges of the dual quarks can be found by imposing that the term $Mq\tilde{q}$ of (2.44) has R-charge two. In this way, we found the R-charges at the superconformal infrared fixed point.

Phases of the magnetic theory

In order to study the phases of the dual theory we can map the various ranges of flavours of the electric theory into ranges for the magnetic theory by considering the relation $\tilde{N}_c = N_f - N_c$

Electric	$N_c + 2 \leq N_f \leq \frac{3}{2}N_c$	$\frac{3}{2}N_c < N_f < 3N_c$	$N_f \geq 3N_f$
Magnetic	$N_f \geq 3N_c$	$\frac{3}{2}N_c < N_f < 3N_c$	$N_c + 2 \leq N_f \leq \frac{3}{2}N_c$

(2.46)

As we can see from the table, both the electric and magnetic theories are in the conformal windows for the same values of N_f, N_c . In the other two intervals, the dual theories are in opposite phases.

For $N_c + 2 \leq N_f \leq \frac{3}{2}N_c$ the electric theory is strongly coupled and we can't describe its dynamics. On the other hand, the magnetic theory is free and can be used to describe the physics for this range of flavours.

When the electric theory is in a free non-Abelian phases ($N_f \geq 3N_c$), the magnetic theory is strongly coupled.

This feature of Seiberg duality is particularly useful, because it gives us a weakly coupled description of a strongly-coupled theory.

Duality

In the *conformal window* the electric and magnetic theories we introduced previously give an equivalent description of the same physics in the infrared. In

this range, the magnetic theory has a non-trivial infrared fixed point too. At this fixed point, the superpotential (2.44) is a relevant perturbation because it has dimension $D = 1 + 3\frac{N_c}{N_f} < 3$ and it drives the theory to a new fixed point. Electric mesons have different dimension in the UV from the magnetic ones because they are constructed from a pair of electric quarks. For this reason it is necessary to introduce an energy scale μ in order to match their dimension in the UV: $M = \mu M_m$, where M_m are the magnetic mesons. The matching of the scales between the electric and magnetic theory results in the following relation between them [8]

$$\Lambda^{3N_c - N_f} \tilde{\Lambda}^{3(N_f - N_c) - N_f} = (-1)^{N_f - N_c} \mu^{N_f} \quad (2.47)$$

The consequences of this equation are that when one theory is strongly coupled, the other is weakly coupled, as we noted in the previous section. Moreover, it ensures that the dual of the dual theory is the electric theory itself. The dual of the dual magnetic theory is a $SU(N_c)$ $SQCD$ theory with scale Λ , d^i and $\tilde{d}_{\tilde{j}}$ quarks and additional singlets M_j^i and $N_i^{\tilde{j}} = q_i \tilde{q}^{\tilde{j}}$ with superpotential

$$W = \frac{1}{\tilde{\mu}} N_i^{\tilde{j}} d^i \tilde{d}_{\tilde{j}} + \frac{1}{\mu} M_j^i N_i^{\tilde{j}} = \frac{1}{\mu} N_i^{\tilde{j}} (-d^i \tilde{d}_{\tilde{j}} + M_j^i) \quad (2.48)$$

considering that from the previous relation we have $\tilde{\mu} = -\mu$.

Meson fields are massive and can be integrated out by using their equation of motion, which result in

$$N_i^{\tilde{j}} = 0 \quad M_j^i = d^i \tilde{d}_{\tilde{j}} \quad (2.49)$$

Considering that the dual theories describe the same physics, there should be a mapping of gauge invariant operators between them. We already saw that electric and magnetic mesons match in the infrared. A mapping should exist also for baryonic operators. Indeed it does and it is given by

$$\begin{aligned} B^{i_1 \dots i_{N_c}} &= C \epsilon^{i_1 \dots i_{N_c} j_1 \dots j_{N_f - N_c}} b_{j_1 \dots j_{N_f - N_c}} \\ \tilde{B}^{i_1 \dots i_{N_c}} &= C \epsilon_{i_1 \dots i_{N_c} \tilde{j}_1 \dots \tilde{j}_{N_f - N_c}} \tilde{b}_{\tilde{j}_1 \dots \tilde{j}_{N_f - N_c}} \\ \text{where} \quad C &= \sqrt{-(-\mu)^{N_c - N_f} \Lambda^{3N_c - N_f}} \end{aligned} \quad (2.50)$$

using (2.47) it can be shown that these mappings preserve the involutive action of the duality.

As an additional check of the duality, 't Hooft anomaly matching conditions have been calculated in [8] for the electric and magnetic theories for the various

global symmetries and in both theories they are given by

$$\begin{aligned}
SU(N_f)^3 &\longrightarrow N_c \\
U(1)_R SU(N_f)^2 &\longrightarrow -\frac{N_c^2}{2N_f} \\
U(1)_B SU(N_f)^2 &\longrightarrow \frac{N_c}{2} \\
U(1)_R &\longrightarrow -N_c^2 - 1 \\
U(1)_R^3 &\longrightarrow -N_c^2 - 1 - 2\frac{N_c^4}{N_f^2} \\
U(1)_B^2 U(1)_R &\longrightarrow -2N_c^2
\end{aligned} \tag{2.51}$$

Another important check of the duality is that it remains valid under mass perturbations of the electric theory. Suppose to add a superpotential term that gives mass to the quark in the last flavour and is equal to

$$W_{mass}^{el} = m Q_{N_f} \tilde{Q}^{N_f} \tag{2.52}$$

Flowing to the IR the number of quarks is decreased by one, driving the theory to a more strongly coupled fixed point⁴. The new scale of the theory is given in terms of the old one by

$$\Lambda_L^{3N_c - (N_f - 1)} = m \Lambda^{3N_c - N_f} \tag{2.53}$$

In the magnetic theory the mass perturbation is mapped in the term

$$W_{mass}^{mag} = m M_{N_f}^{N_f} \tag{2.54}$$

Because of this term, the gauge group gets higgsed to $SU(N_f - 1 - N_c)$ and only $N_f - 1$ light quarks remain in the theory.

The scale of the magnetic theory Λ_L is modified and reads

$$\tilde{\Lambda}^{3(N_f - N_c - 1) - (N_f - 1)} = -\frac{\tilde{\Lambda}^{3(N_f - N_c) - N_f}}{\langle q_{N_f} \tilde{q}^{N_f} \rangle} \tag{2.55}$$

where $\langle q_{N_f} \tilde{q}^{N_f} \rangle = -\mu m$ because of the equation of motion for the massive flavour.

As expected the magnetic theory becomes more weakly coupled.

We conclude that the duality is preserved under massive deformations.

2.3 Kutasov-Schwimmer-Seiberg duality

A possible generalization of Seiberg duality can be found by adding matter fields in different representations of the gauge group. Kutasov, Schwimmer and Seiberg ([15], [16], [17]) considered $SU(N)$ SQCD with the addition of a matter field in the adjoint representation of the gauge group and found that it admitted a magnetic dual.

⁴Considering that matter in the fundamental representation contributes with a positive term it is easy to see that this is true.

2.3.1 Electric theory

The classical electric theory can be summarized by the following charge table of charges under the global symmetry group $SU(N_f)_L \times SU(N_f)_R \times U(1)_B \times U(1)_R$

	$SU(N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$
Q	N_c	N_f	1	1	$1 - \frac{2}{k+1} \frac{N_c}{N_f}$
\tilde{Q}	$\overline{N_c}$	1	$\overline{N_f}$	-1	$1 - \frac{2}{k+1} \frac{N_c}{N_f}$
X	$N_c^2 - 1$	1	1	0	$\frac{2}{k+1}$

(2.56)

and by the addition of the superpotential

$$W_{Adj} = g_k \text{Tr } X^{k+1} \quad (2.57)$$

The superpotential (2.57) drives the theory to a new infrared fixed point. It is either relevant or dangerously irrelevant, depending on the value of k [16].

Being dangerously irrelevant means that in the ultraviolet it is an irrelevant term, whose coupling gets weaker along the renormalization group flow. However, at some point in the flow, the fields acquire a dimension such that it becomes a relevant perturbation, getting stronger along the flow and driving the theory to a different fixed point in the infrared.

The theory possesses two different R-symmetries but the superpotential breaks explicitly one of them and imposes that the adjoint matter field has R-charge $\frac{2}{k+1}$.

The remaining R-charges can be fixed by imposing that the R-symmetry is anomaly free as we did previously. Using formula (2.17), considering also the fermion in the adjoint matter multiplet we have

$$\begin{aligned} N_c + (R_Q - 1) \frac{1}{2} 2N_f + (R_X - 1)N_c &= 0 \\ (R_Q - 1)N_f = -R_X N_c &\longrightarrow R_Q = 1 - R_X \frac{N_c}{N_f} \end{aligned} \quad (2.58)$$

Imposing this condition the R-charges of the fields were fixed completely, as in Seiberg duality. This has been possible because the superpotential (2.57) fixed independently the R-charge R_X . Otherwise the condition (2.58) fixes R_Q as a function of R_X with R_X generic.

The gauge invariant operators that can be constructed are mesons and baryons multiplied with powers of the adjoint field. Meson operators are given by

$$(M_j)_i^j = \tilde{Q}_i X^j Q^i \quad j = 0, 1, \dots, k-1 \quad (2.59)$$

Baryons are more easily introduced by first defining "dressed quarks"

$$Q_{(l)} = X^l Q \quad l = 0, \dots, k-1 \quad (2.60)$$

Baryons are defined as

$$B^{i_1, i_2, \dots, i_k} = Q_{(0)}^{i_1} \dots Q_{(k-1)}^{i_k} \quad \text{with } \sum_{l=1}^k i_l = N_c \quad (2.61)$$

with color indices contracted with an ϵ tensor.

Vacuum structure

In analogy with the condition $N_f \geq N_c$ in $SQCD$ we would like to find a range of values of N_f, N_c and k such that the theory admits stable vacua. We can add a weak deformation to the superpotential (2.57), by adding terms with lower order powers in X

$$W(X) = \sum_{l=1}^k g_l \text{Tr } X^{l+1} + \lambda \text{Tr } X \quad \text{with } g_l \ll 1 \quad (2.62)$$

where we introduced λ as a Lagrange multiplier to enforce the tracelessness of X . Considering that it is a weak perturbation, the large field behavior of the superpotential is not modified. Hence, if we cannot find stable vacua with the weak perturbation, the original theory doesn't have any vacua too.

The theory has a large set of multiple vacua for $Q = \tilde{Q} = 0$ and $X \neq 0$. X can be diagonalized with eigenvalues x_i . The F-terms are given by setting $W'(x_i) = 0$. Now, $W'(x_i)$ is a polynomial of degree k in the eigenvalues x_i admitting k distinct solutions in general. As a result, ground states are labeled by a set of k integers (i_1, \dots, i_k) , describing how many eigenvalues are in the l -th minimum. Clearly, considering that X has N_c eigenvalues we have

$$\sum_{l=1}^k i_l = N_c \quad (2.63)$$

In every vacuum, X has a quadratic potential, which corresponds to a mass term and can be integrated out. The X expectation values break the gauge group in the following way

$$SU(N_c) \longrightarrow SU(i_1) \times SU(i_2) \times \dots \times SU(i_k) \times U(1)^{k-1} \quad (2.64)$$

Each $SU(i_l)$ sector describes a decoupled $SQCD$ model which has stable vacua only if $N_f \geq N_c$, hence considering every sector we have

$$i_l \leq N_f \quad \forall 1 \leq l \leq k \quad (2.65)$$

Taking the limit $g_l \rightarrow 0$ we find that we must have

$$N_f \geq \frac{N_c}{k} \quad (2.66)$$

For every choice of i_l there is a moduli space obtained by giving expectation values to the quarks. Hence, the moduli space of the theory consists of different disconnected components, associated to different choice of i_l .

2.3.2 Magnetic theory

The magnetic theory is constructed in a similar way as the magnetic theory in Seiberg duality. The dual theory has gauge group $SU(\tilde{N}_c) = SU(kN_f - N_c)$.

The baryonic charge of the dual quarks is found by imposing that baryons in the electric theory are proportional to the baryons constructed from dual quarks.

	$SU(\tilde{N}_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$
q	\tilde{N}_c	\overline{N}_F	1	$\frac{N_c}{kN_f - N_c}$	$1 - \frac{2}{k+1} \frac{\tilde{N}_c}{N_f}$
\tilde{q}	$\overline{\tilde{N}_c}$	1	N_F	$-\frac{N_c}{kN_f - N_c}$	$1 - \frac{2}{k+1} \frac{\tilde{N}_c}{N_f}$
Y	1	$\tilde{N}_c^2 - 1$	1	0	$\frac{2}{k+1}$
M_j	1	N_f	\overline{N}_f	0	$2 - \frac{4}{k+1} \frac{N_c}{N_f} + j \frac{2}{k+1}$

(2.67)

The magnetic theory has a superpotential

$$W = \text{Tr } Y^{k+1} + \sum_{j=0}^{k-1} M_j q Y^{k-j-1} \tilde{q} \quad \text{dove } M_j = Q Y^j \tilde{Q} \quad (2.68)$$

The charges of the fields are easily found by requiring duality for the two theories. In this way, the charges of the mesons are given in terms of the electric quarks, which are fixed, and the superpotential fixes the charges for the remaining fields. Using this method, the R-charges of the dual quarks are given by

$$R_q = R_X - R_Q \quad (2.69)$$

where we used that $R_X = R_Y = \frac{2}{k+1}$ because of (2.68) and (2.57).

Duality and mass deformations

Similarly to Seiberg duality, the duality is valid in a range of (N_f, N_c) in which both the electric and magnetic theory are asymptotically free. In that window, the superpotentials $\text{Tr } X^{k+1}$ and $\text{Tr } Y^{k+1}$ are both relevant in the infrared. An estimate of the window is given in [18] through a-maximization.

The mapping of gauge invariant operators between the two theories is given by

$$\begin{aligned} X &\longleftrightarrow Y \\ QX^j \tilde{Q} &\longleftrightarrow M_j \\ B_{el}^{(i_1, i_2, \dots, i_k)} &\longleftrightarrow B_{mag}^{(j_1, j_2, \dots, j_k)} \end{aligned} \quad (2.70)$$

where $j_l = N_f - i_{k+1-l}$ and $l = 1, \dots, k$.

The charge assignment necessary for the mapping of the operators is consistent

with 't Hooft anomaly matching conditions which are given by

$$\begin{aligned}
SU(N_f)^3 &\longrightarrow N_c d^{(3)}(N_f) \\
U(1)_R SU(N_f)^2 &\longrightarrow -\frac{2}{k+1} \frac{N_c^2}{N_f} d^{(2)}(N_f) \\
SU(N_f)^2 U(1)_B &\longrightarrow N_c d^{(2)}(N_f) \\
U(1)_R &\longrightarrow -\frac{2}{k+1} (N_c^2 + 1) \\
U(1)_R^3 &\longrightarrow \left(\left(\frac{2}{k+1} - 1 \right)^3 + 1 \right) (N_c^2 - 1) - \frac{16}{(k+1)^3} \frac{N_c^4}{N_f^2} \\
U(1)_B^2 U(1)_R &\longrightarrow -\frac{4}{k+1} N_c^2
\end{aligned} \tag{2.71}$$

We consider now mass deformations of the electric theory in order to understand if duality is preserved under such deformations. Let's modify the electric superpotential by adding a mass term

$$W_{el} = g_k \text{Tr} X^{k+1} + m \tilde{Q}_{N_f} Q^{N_f} \tag{2.72}$$

The number of flavours in the infrared is reduced by one unit. In order to preserve the duality, the magnetic theory should have gauge group $SU(k(N_f - 1) - N_c) = SU(kN_f - N_c - k)$. Let's see if this is the case. The dual potential reads

$$W_{mag} = g_k \text{Tr} Y^{k+1} + \sum_{j=1}^k M_j \tilde{q} Y^{k-j-1} q + m (M_0)_{N_f}^{N_f} \tag{2.73}$$

Integrating out the massive fields we find

$$q_{N_f} Y^l \tilde{q}^{N_f} = -\delta_{l,k} m \quad l = 0, \dots, k-1 \tag{2.74}$$

which fixes the expectation values to

$$\begin{aligned}
\tilde{q}_\alpha^{N_f} &= \delta_{\alpha,1} \\
q_\alpha^{N_f} &= \delta^{\alpha,k} \\
Y_\beta^\alpha &= \begin{cases} \delta_{\beta+1}^\alpha & \beta = 1, \dots, k-1 \\ 0 & \text{otherwise} \end{cases}
\end{aligned} \tag{2.75}$$

These expectation values break the gauge group to $SU(kN_f - N_c) \rightarrow SU(k(N_f - 1) - N_c)$ through the Higgs mechanism and reduces the number of flavours by one unit as required by duality. As a result, duality is preserved under mass deformations.

Chapter 3

Three dimensional dualities

3.1 Supersymmetric field theories in three dimensions

Spinors in three dimensions have different properties than their four dimensional counterpart.

The dimension of the representation in an arbitrary dimension D is given by $2^{\frac{D}{2}}$ for D even, while $2^{\frac{D-1}{2}}$ for D odd. Hence, in three dimension we have a two dimensional representation. In odd dimensions representations are irreducible and Weyl spinors do not exist: the chirality operator (γ_{D+1} or γ^*) is proportional to the identity.

Gamma matrices can be chosen real and the Majorana condition can be imposed, lowering the degrees of freedom of the representation from four to two. Moreover, in three dimensions spinors have only undotted indices, since the covering group of $SO(3)$ is $SU(2)$.

In our notation the supercharges are complex, while minimal spinors in three dimensions are real, therefore resulting in $\mathcal{N} = 2$ theories. Since $3d \mathcal{N} = 2$ theories have four supercharges, we can use the $4d \mathcal{N} = 1$ superspace formalism. The supersymmetry algebra and its representations can be found by dimensional reduction from four dimensions. It is given by

$$\{Q_\alpha, Q_\beta\} = \{\bar{Q}_\alpha, \bar{Q}_\beta\} = 0 \quad \{Q_\alpha, \bar{Q}_\beta\} = 2\gamma_{\alpha\beta}^\mu P_\mu + 2i\epsilon_{\alpha\beta} Z \quad (3.1)$$

where the central charge Z is the component of the momentum along the reduced direction.

Because of the presence of the central charge in the algebra, now states must satisfy a BPS bound of the form $M \geq Z$, which implies that massless representations have null central charge.

The automorphism of this algebra is $U(1)_R \simeq SO(2)_R$, as in four dimensions. Superspace formalism is similar to what we introduced previously, with proper changes due to the different spinor representations in three dimension such as gamma matrices.

Chiral superfields contain *on-shell* one complex scalar and a complex spinor as in four dimensions.

A Vector superfield contains an additional real scalar field with respect to the four dimensional superfield. The scalar σ comes from the component of the four dimensional vector field A_μ along the reduced direction.

Coulomb branch and dualized photon

In three dimensions a free photon can be dualized to a scalar γ since it has only one polarization. Instead of defining a potential A in order to solve the Bianchi identity $dF = d^2A = 0$, we can define a scalar such that

$$*F = \frac{g^2}{\pi} d\gamma \quad \rightarrow \quad d * F = 0 \quad (3.2)$$

where $*$ is the Hodge operator ¹ and g is the gauge coupling.

The Bianchi identity $dF = 0$ can be seen as a conservation law for the topological current, which is defined as

$$J_\mu^{top} = \frac{1}{2\pi} (*F)_\mu = \frac{1}{2\pi} d\gamma \quad \partial^\mu J_\mu = 0 \quad (3.3)$$

The topological current acts as shifts of the dualized photon $\gamma \rightarrow \gamma + \alpha$.

The quantization of the magnetic flux implies that the dualized photon is periodic and is normalized in such a way that $\gamma \sim \gamma + 2\pi$.

From a vector superfield V we can define a linear multiplet Σ , given by

$$\Sigma = \epsilon^{\alpha\beta} D_\alpha D_\beta V \quad (3.4)$$

It satisfies $D^2\Sigma = 0$ and is gauge invariant under a transformation $V \rightarrow V + i(\Phi - \Phi^\dagger)$. The lowest component of Σ is the scalar in the vector multiplet. It contains also a term $\bar{\theta}\sigma_\rho\theta \epsilon^{\mu\nu\rho} F_{\nu\rho}$, which is proportional to the topological current. The super Yang-Mills action can be written as

$$S \sim \int d^4\theta \Sigma^2 \quad (3.5)$$

The vacuum expectation values of scalar fields in the vector multiplet parametrize a subset of the moduli space of the theory which is called the *Coulomb branch*. Using the dualized photon we can turn the vector multiplet into a chiral multiplet, whose lowest component is a good parametrization of the Coulomb branch

$$Y = \exp\left(\frac{2\pi\sigma}{g^2} + i\gamma\right) \quad (3.6)$$

¹ The Hodge operator acts on p -forms in a n dimensional manifold. For a p -form ω its action is given by

$$(*\omega)_{\mu_1 \dots \mu_{n-p}} = \frac{\sqrt{g}}{p!} \epsilon_{\mu_1 \dots \mu_n} g^{\mu_{n-p+1} \nu_1 \dots \mu_n \nu_p} \omega_{\mu_1 \dots \mu_p}$$

because of its periodicity, it's natural to assign γ to a phase factor.

The classical lagrangian term of matter multiplets in representations R_f of the gauge group is

$$\sum_f \int d^4\theta Q_f^\dagger e^V Q_f \quad (3.7)$$

The dualization of the photon is possible as long there is no matter in the theory. The expansion of V contains a term $\sigma\theta\bar{\theta}$ which give rise to a potential term for the squarks of the form

$$\sum_f |\sigma Q_f|^2 \quad (3.8)$$

As a result, matter fields couple with σ with mass terms. If we consider a generic point of the Coulomb branch, all charged matter fields are massive and can be integrated out. Therefore, in a low-energy description we can still dualize the gauge field.

A similar reasoning can be applied to non-Abelian gauge theories. In fact, in a generic point of the Coulomb branch, the VEV of σ breaks the gauge group to its maximal torus $U(1)^{r_G}$, where r_G is the rank of the gauge group. We now have r_G massless vector multiplets that can be dualized into chiral multiplets Y_i with $i = 1, \dots, r_G$.

Note that since the definition of Y depends on the gauge coupling, it will be modified by quantum corrections.

For $SU(N)$ theories it's better to use the following coordinates on the Coulomb branch, because they are related to the simple roots of the algebra

$$Y_k \sim \exp \left(\frac{\sigma_j - \sigma_{j+1}}{\hat{g}^2} + i(\gamma_j - \gamma_{j+1}) \right) \quad \hat{g}^2 = \frac{g^2}{4\pi} \quad (3.9)$$

with $j = 1, \dots, N - 1$.

From now on we choose a Weyl chamber by setting $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_N$ with a Weyl transformation.

For $SU(N)$ gauge theories is useful to define

$$Y = \prod_{j=1}^{r_G} Y_k \quad (3.10)$$

since it will be a coordinate of the unlifted Coulomb branch for such theories. For $U(N)$ theories we will use the following chiral fields as coordinates on the Coulomb branch

$$X_i \sim \exp \left(\frac{\sigma_i}{g^2} + i\gamma_i \right) \quad \text{for } i = 1, \dots, N \quad (3.11)$$

Real masses

In $3D \mathcal{N} = 2$ theories there's another way to give a mass to a chiral multiplet other than with the superpotential term $W_{mass} = m\Phi^2$, which corresponds to a

holomorphic mass.

In these theories we can couple a global symmetry, which is not a R-symmetry, to a background vector multiplet. If we give a vacuum expectation value \hat{m} to the scalar in the multiplet each field charged under that symmetry will receive a mass $q\hat{m}$, where q is the charge of the field under that symmetry. If a chiral field is charged under different global symmetry, its mass will be a sum of the real masses for every gauged global symmetry. Real masses are parity odd and belong to vector multiplets rather than chiral fields. For this reason, they cannot appear in holomorphic objects such as the superpotential.

In addition, real masses relative to global abelian symmetries contribute to the central charge of the supersymmetry algebra Z through

$$Z = \sum q_i m_i \quad (3.12)$$

where q_i is the charge of the field and m_i the real masses under a global symmetry $U(1)_i$.

Moreover, the central charge Z can be promoted to a background linear superfield whose lowest component is Z .

Another symmetry that can contribute to the central charge is the topological symmetry $U(1)_J$, whose current is given by the linear multiplet Σ we defined in (3.4).

The additional term is given by $\int d^4\theta V_b \Sigma$, where V_b is a background vector multiplet. Integrating by parts and defining $\Sigma_b = \epsilon^{\alpha\beta} D_\alpha D_\beta V_b$ we obtain $\int d^4\theta \Sigma_b V$. Thus, the scalar component of the background vector field ξ is a Fayet-Iliopoulos term for the vector superfield. It contributes to the central charge with a mass $m_J = \xi$.

Monopoles

In three dimensions there exist finite energy solutions that can be understood in terms of four dimensional monopoles after compactifying one direction. The scalar σ will play the role of the scalar Higgs field in the adjoint representation typically used to introduce monopoles [19]. Different topological solutions can be found since the scalar field at infinity must approach a vacuum solution. Such a solution doesn't have to be the same in every direction and as a result we find different topological solutions depending on how we choose to map the two-sphere at infinity to the gauge group G ².

For a generic vacuum expectation value of σ , with $\sigma_i \neq \sigma_j$, the gauge group breaks to its maximal torus $U(1)^{r_G}$. The possible windings around S_∞^2 are then characterized by

$$\Pi_2(G/U(1)^{r_G}) = \Pi_1(U(1)^{r_G}) = \mathbb{Z}^{r_G} \quad (3.13)$$

The equality holds if $\Pi_2(G) = 0$, which is true for every semisimple group and if $\Pi_1(G) = 0$, which is satisfied if the group is the covering group of the Lie

²The mapping relates S_∞^2 to the gauge group rather than S_∞^3 since monopoles are localized in space rather than in space-time.

algebra [19]. As a result there are r_G different topological solutions. Each of these solutions carry a magnetic charge for each of the $U(1)^{r_G}$ unbroken gauge fields. For example, for $G = SU(N_c)$ we have $N_c - 1$ different topological solutions. For $SU(2)$ gauge group one solution to the equations is given by the 't Hooft-Polyakov monopole, which in singular gauge reads [20]

$$\sigma = \left(v \coth(vr) - \frac{1}{r} \right) \tau^3 \quad A_\mu = \epsilon_{ij3} \hat{r}^i \left(\frac{1}{r} + \frac{v}{\sinh(vr)} \right) \quad (3.14)$$

This solution can be easily extended to $SU(N)$ gauge group by embedding the above solutions in a $SU(2)$ subgroup of the gauge group. Since the gauge group is broken in the vacuum, we cannot use $SU(N)$ gauge transformations to generate other solutions. As a result, each embedding of $SU(2)$ will result in a monopole charged under different $U(1)$ factors of the Cartan. Note that there are $N - 1$ special embeddings of $SU(2)$ into $SU(N)$ which result in monopoles charged only under one factor of the $U(1)$ in the Cartan subalgebra. They are given by the $N-1$ contiguous 2×2 blocks in the diagonal.

The importance of monopole operators in three dimensions is due to the fact that flowing to the infrared, they flow to the coordinates on the Coulomb branch we introduced in (3.9) for $SU(N)$ theories [21].

The charges of the monopoles can be written as

$$\vec{g} = 2\pi \sum_a n_a \vec{\alpha}_a \quad (3.15)$$

where $\vec{\alpha}_a$ are the simple roots of the $su(N)$ Lie algebra. Dirac quantization condition imposes that $n_a \in \mathbb{Z}$.

Moreover, the mass of the monopoles is subject to the BPS bound which is given by

$$M_{monopole} \geq \frac{|\vec{g} \cdot \sigma|}{e^2} = \frac{2\pi}{e^2} \sum_i n_i \sigma_i \quad (3.16)$$

where σ_i are the vacuum expectation values of σ . Monopoles that saturate the bound are called BPS monopoles.

3.1.1 Moduli spaces of gauge theories

The moduli space of three dimensional gauge theories is qualitatively different from four dimensional theories.

The presence of the scalar field in the vector multiplet results in an additional branch of the moduli space which is called *Coulomb branch*. Non-perturbative effects generated by instantons will in general remove a part of the Coulomb branch from the moduli space. However in most dualities, the Coulomb branch will be completely lifted.

The branch of the moduli space associated to the squarks is called Higgs branch and it is parametrized by mesons and, if they can be constructed, by baryons.

Moduli space of $U(1)$ gauge theory with N_f massless flavours

For large values of σ , the Coulomb branch of the theory can be parametrized by the chiral superfield we defined in previous section as $X = \exp\left(\frac{2\pi\sigma}{g^2} + i\gamma\right)$, which corresponds to a cylinder. However, the metric for γ receives quantum correction and thus the topology of moduli space is changed by quantum effects. The Higgs branch intersects the Coulomb branch for $\sigma = 0$ and since the latter is invariant under $U(1)_J$, which acts as a shift on γ , the radius of the circle must shrink to zero where they intersect.

Therefore, near the origin the moduli space looks like the intersection of three cones: the Higgs branch and two cones, which correspond to the two distinct parts of the Coulomb branch as in figure 3.1. Half of the Coulomb branch is parametrized semi-classically by the field $V_+ \sim e^{\frac{\Phi}{g^2}}$, while the other half by $V_- \sim e^{-\frac{\Phi}{g^2}}$.

Figure 3.1: Schematic picture of the origin of the moduli space for a $U(1)$ gauge theory.

Two different chiral fields are needed since near the origin the moduli space shrinks to a point and $V_+ \rightarrow 0$. The Higgs branch is not modified by quantum corrections and the mesons can still be used to parametrize it.

The charges of the fields under the symmetries are given by

	$U(1)_R$	$U(1)_J$	$U(1)_A$	$SU(N_f)_R$	$SU(N_f)_L$
Q	0	0	1	N_f	1
\tilde{Q}	0	0	1	1	$\overline{N_f}$
V_{\pm}	N_f	± 1	$-N_f$	1	1

(3.17)

The symmetries force the superpotential to have the form

$$W = -N_f (V_+ V_- \det(M))^{\frac{1}{N_f}} \quad (3.18)$$

The superpotential is singular at the origin of the moduli space because of the presence of the root, indicating that there are massless degrees of freedom that need to be taken into account.

We can give real masses \bar{m}_i ($-\bar{m}_i$) to the quarks Q_i (\tilde{Q}_i). The Higgs branch is parametrised by the diagonal elements of M_i^i which intersects the Coulomb branch at $\sigma = \bar{m}_i$. At every intersection, we have $U(1)$ theory with one flavour. The coulomb branch is parametrised, at every intersection, by $V_{i,\pm} = e^{\pm \frac{\Phi - \bar{m}_i}{g^2}}$ with a superpotential given by

$$W = - \sum_{i=1}^{N_f} M_i^i V_{i,+} V_{i,-} + \sum_{i=1}^{N_f-1} \lambda_i (V_{i,+} V_{i+1,-} - 1) \quad (3.19)$$

where λ_i are Lagrange multipliers in order to enforce the semiclassical identification $V_{i,+} V_{i+1,-} = 1$.

Figure 3.2: Moduli space of vacua for SQED with four flavours

Moduli spaces for $SU(N_c)$ theories with $N_c > 2$ and with N_f flavours

We will consider a $SU(N_c)$ gauge theory with equal number of Q and \tilde{Q} . The symmetries of the theory are given by the following table

	$U(1)_R$	$U(1)_B$	$U(1)_A$	$SU(N_f)_L$	$SU(N_f)_R$
Q	0	1	1	N_f	1
\tilde{Q}	0	-1	1	1	$\overline{N_f}$
M	0	0	2	N_f	$\overline{N_f}$
$Y_{j \neq K}$	-2	0	0	1	1
Y_K	$2(N_f - 1)$	0	$-2N_f$	1	1
Y	$2(N_f - N_c + 1)$	0	$-2N_f$	1	1

(3.20)

where Y_j are defined as in (3.9) and Y is defined as $Y = \prod_{j=1}^{N_c-1} Y_j \sim e^{\frac{\Phi_1 - \Phi_{N_c}}{g^2}}$. The VEVs of the adjoint scalar are ordered in such a way that $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_{N_c}$. The value of j for which σ changes sign is called K . In a generic point of the Higgs branch, the gauge group is $SU(N_f - N_c)$ for $N_f < N_c - 1$ and it breaks completely for $N_f \geq N_c - 1$. As in four dimensions the Higgs branch is parametrized by mesons and, for $N_f \geq N_c$, by baryons too.

For theories without quarks, instantons generate the Affleck-Harvey-Witten [22] superpotential

$$W = \sum_{j=1}^{N_c-1} \frac{1}{Y_j} \quad (3.21)$$

which prohibits the theory to have stable supersymmetric vacua by lifting completely the Coulomb branch.

The theory with massless quarks features a superpotential generated by $N_c - 2$ instantons

$$W_{inst} = \sum_{j \neq K} \frac{1}{Y_j} \quad (3.22)$$

which doesn't completely lift the Coulomb branch. In fact, the following subspace is not lifted by the AHW superpotential (3.21)

$$\sigma_1 > \sigma_2 = \dots = 0 > \sigma_{N_c} = -\sigma_1 \quad (3.23)$$

The last equality holds because we have $\sum_i \sigma_i = 0$ for $SU(N_c)$ gauge group. The quantum corrected moduli space is different from the classical one and for $N_f < N_c - 1$ the only effective superpotential which is compatible with the symmetries of the theory is given by [23]

$$W_{eff} = (N_c - N_f - 1)(Y \det(M))^{\frac{1}{N_f - N_c + 1}} \quad (3.24)$$

which admits no stable vacuum.

For $N_f = N_c - 1$ the effective superpotential defined above is not defined. For these values we have a constraint on the moduli space given by [23]

$$Y \det(M) = 1 \quad (3.25)$$

which results in a merging between the Higgs and the Coulomb branch.

For $N_f \geq N_c$, the low-energy description contains baryons. The quantum moduli space is the same as the semi-classical moduli space and there is a superconformal fixed point at the origin. In the $N_f = N_c$ case an effective description of the moduli space can be given and the superpotential is [23]

$$W = -Y(\det(M) - B\tilde{B}) \quad (3.26)$$

which forces the theory to flow to a non-trivial fixed point in the infrared.

For $N_f > N_c$ an effective description is not known.

The above analysis can be extended to theories with $U(N_c)$ gauge group with $N_f \leq N_c$. We will discuss the theory with $N_f = N_c$ because the results with lower number of flavours can be obtained by integrating out quarks.

The theory with $U(N_c)$ is obtained by gauging the global $U(1)_B$ factor.

Given that we have $N_f = N_c$, the superpotential (3.26) from the $SU(N_c)$ part of the group is present and for the $U(1)$ factor we have one flavour given by $X = B\tilde{B}$ and chiral fields V_+ , V_- , defined as

$$V_+ \sim \exp\left(\frac{\Phi_1}{g^2} + i\gamma_1\right) \quad V_- \sim \exp\left(\frac{\Phi_{N_c}}{g^2} + i\gamma_{N_c}\right) \quad (3.27)$$

because the null trace condition does not hold any more.

The $U(1)$ sector has a superpotential given by

$$W = -XV_+V_-$$

As a result, the superpotential for the theory is given by

$$W = -Y(\det(M) - X) - XV_+V_- \quad (3.28)$$

Integrating out the massive field Y we obtain a superpotential

$$W = -V_+V_-\det(M) \quad (3.29)$$

3.2 Aharony duality

One of the first three dimensional dualities was found by Aharony [24] and Karch [25] for theories with gauge group $U(N_c)$ and non-chiral matter in the fundamental representation. The charges of the fields are given by the following table

	$U(1)_R$	$U(1)_A$	$U(1)_J$	$SU(N_f)_L$	$SU(N_f)_R$
Q	0	1	0	N_f	1
\tilde{Q}	0	1	0	1	$\overline{N_f}$
M	0	2	0	1	1
V_\pm	$N_f - N_c + 1$	$-N_f$	± 1	1	1

(3.30)

where V_\pm are defined as in the previous section and parametrize the unlifted Coulomb branch. The R-charges of the quarks have been fixed to zero in order to have the fermion in the multiplet with R-charge -1 . The moduli space of this theory was described in the previous section.

The dual theory is a $U(\tilde{N}_c) = U(N_f - N_c)$ gauge theory with N_f flavours q, \tilde{q} and with the addition of singlet fields M, V_+, V_- with the same quantum number of the electric theory. The charges are chosen in order to be consistent with a potential $W = M q \tilde{q}$ as in four dimensional dualities.

The global charges of the theory are given by

	$U(1)_R$	$U(1)_A$	$U(1)_J$	$SU(N_f)_L$	$SU(N_f)_R$
q	1	-1	0	N_f	1
\tilde{q}	1	-1	0	1	N_f
\tilde{V}_\pm	$N_c - N_f - 1$	N_f	± 1	1	1

(3.31)

The magnetic theory features a superpotential of the form

$$W = M_i^{\tilde{j}} q^i \tilde{q}_{\tilde{i}} + V_+ \tilde{V}_- + V_- \tilde{V}_+ \quad (3.32)$$

The dual theory now contains the fields V_+, V_- which are matched with the coordinate on the Coulomb branch of the electric theory. Consider that in three dimensions the moduli space contains the Coulomb branch, which wasn't present in four dimensional theories. The introduction of the monopoles is crucial in order to have the same moduli space between the two theories.

The dual theory exists only for $N_f > N_c$. Starting with $N_f = N_c + 1$ we obtain a dual theory with $U(1)$ gauge group. Adding a mass term of the form mM in the dual theory breaks the gauge group. After integrating out quarks and \tilde{V}_\pm fields we obtain an effective description given only by mesons and V_\pm with no other fields. The superpotential is constrained by symmetries to be of the form

$$W = -V_+ V_- \det(M) \quad (3.33)$$

We found exactly the dual description of the theory we introduced in (3.29) for the case $N_f = 1$.

We can compare the moduli space between the dual theories by looking at specific vacua. For example, let's consider a point on the Higgs branch in the electric theory with vacuum expectation values of the mesons of rank N_c . The low-energy dual theory associated to such a VEV is a $U(N_f - N_c)$ theory with $N_f - N_c$ massless flavours whose moduli space can be described by a superpotential of the form $W = \tilde{V}_+ \tilde{V}_- \det(q\tilde{q})$ since $N_f = \tilde{N}_c$.

The equations of motion resulting from the addition of this term to the superpotential (3.32) set $V_+ = V_- = 0$, as in the electric theory.

3.3 Kim-Park duality

Aharony duality can be generalized with the addition of a field in the adjoint representation [26].

The electric theory contains N_f flavours and a chiral multiplet in the adjoint representation. The theory has a superpotential given by $W = \text{tr} X^{k+1}$ that fixes the R-charge of the field to $\Delta_X = \frac{2}{k+1}$. The R-charges of the quarks have been left unconstrained to the generic value Δ_Q .

The charges of the fields are given by

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_A$	$U(1)_J$	$U(1)_R$
Q	N_f	1	1	0	Δ_Q
\tilde{Q}	1	$\overline{N_f}$	1	0	Δ_Q
X	1	1	0	0	$\frac{2}{k+1}$
$v_{j,\pm}$	1	1	$-N_f$	± 1	$-N_f(\Delta_Q - 1) - \frac{2}{k+1}(N_c - 1 - j)$

(3.34)

where $v_{j,\pm}$ with $j = 0, \dots, k-1$ are the monopole operators dressed with powers of the adjoint field. They are defined as [26]

$$v_{j,\pm} = \text{Tr}(v_{0,\pm} X^j) \quad (3.35)$$

where $v_{0,\pm}$ is the bare monopole operator we defined in the previous section in (3.11).

To see the reason why there are k different monopoles in this theory we can

weakly deform the superpotential to a generic polynomial, as we did in (2.62). The effect of this deformation is the breaking of the gauge group $U(N_c)$ in

$$U(N_c) \rightarrow U(r_1) \times U(r_2) \times \cdots \times U(r_k) \quad \text{with} \quad \sum r_i = N_c \quad (3.36)$$

Following the same reasoning, in the infrared we find k distinct SQCD sectors with gauge group $U(r_i)$ without adjoint matter, since it has been integrated out. Every sector must have a pair of monopoles since it is a $U(r_i)$ theory, as we have seen in section 3.1.1.

Going to the limit of vanishing coupling we find that the original theory have k pairs of monopole operators.

The magnetic theory is a $U(kN_f - N_c)$ gauge theory with N_f dual quarks (q, \tilde{q}) , adjoint matter Y and singlet fields $(M_j)_i^i$ and $v_{j,\pm}$. Mesons are constructed from the quarks and the adjoint matter in the electric theory and the $v_{j,\pm}$ are the electric monopole operators.

The charges of the fields are given by

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_A$	$U(1)_J$	$U(1)_R$
q	N_f	1	1	0	Δ_q
\tilde{q}	1	$\overline{N_f}$	1	0	Δ_q
Y	1	1	0	0	$\frac{2}{k+1}$
M_j	N_f	$\overline{N_f}$	2	0	$2\Delta_Q + j\frac{2}{k+1}$
$v_{j,\pm}$	1	1	$-N_f$	± 1	$-N_f(\Delta_Q - 1) - \frac{2}{k+1}(N_c - 1 - j)$
$\tilde{v}_{j,\pm}$	1	1	N_f	± 1	$N_f(\Delta_Q - 1) + \frac{2}{k+1}(N_c + 1 + j)$

(3.37)

The fields $\tilde{v}_{j,\pm}$ are the monopole operators of the magnetic theory and are constructed in the same way of the electric ones. The charges of the dual quarks and of the adjoint matter are chosen in order to be compatible with a superpotential

$$W = \text{Tr} Y^{k+1} + \sum_{j=0}^{k-1} M_j \tilde{q} Y^{k-j-1} q \quad (3.38)$$

as Kutasov-Schwimmer duality in four dimensions.

The charges of the monopole operators can be calculated by counting their fermion zero modes and are compatible with a superpotential of the form

$$W_{\text{monopoles}} = \sum_{j=0}^{k-1} (v_{i,+} \tilde{v}_{k-j-1,-} + v_{j,-} \tilde{v}_{k-j-1,+}) \quad (3.39)$$

The duality maps the electric adjoint field with the magnetic one. Mesons and monopole operators in the electric theory are mapped as singlets in the magnetic one.

Chapter 4

Reduction of 4D dualities to 3D

In the previous chapters we introduced few examples of electric-magnetic dualities in four and three spacetime dimensions. It is natural to wonder what is the relation between them since they show some similarities but at the same time the dynamics of quantum field theories is different in different spacetime dimensions.

For example, in three dimensions there are no anomalies and the moduli space exhibits a Coulomb branch. Moreover, in three dimensions the axial symmetry is not broken by anomalies and theories may have an additional topological symmetry, associated to abelian factors in the gauge group, which is enforced by a Bianchi identity.

The presence of a scalar field in every vector multiplet allows for real mass terms for fields charged under global symmetries, whereas in four dimensions we could only generate holomorphic mass terms through superpotential terms.

Despite these differences, in general four dimensional dualities can be dimensionally reduced to three dimensions and in some cases the reduction process will unveil new dualities in three dimensions.

4.1 General procedure of reducing dualities

The naïve dimensional reduction of four dimensional dualities, which can be achieved by compactifying a spatial dimension onto S^1 with radius r and then going in the limit $r \rightarrow 0$, in general doesn't result in a three dimensional duality.

Let's analyse the behavior of the theory at finite radius to understand the reasons why the naïve reduction doesn't work.

In four dimensional theories, the strong coupling scale is given by

$$\Lambda^b = \exp\left(-\frac{8\pi^2}{g_4^2}\right) \quad (4.1)$$

where b is the one-loop β function coefficient and we set the renormalization scale μ to 1 for convenience. Recall the following relation for strong coupling scales between dual theories

$$\Lambda^b \tilde{\Lambda}^b = (-1)^{N_f - N_c} \quad (4.2)$$

After compactifying one dimension, the strong coupling scale is modified [21] since $g_4^2 = 2\pi r g_3^2$ and as a result

$$\Lambda^b = \exp\left(-\frac{4\pi}{r g_3^2}\right) \quad (4.3)$$

The consequence of the compactification is that if we take the limit $r \rightarrow 0$, the strong coupling scale goes to zero. Moreover, it's clear that the relation between strong coupling scales of dual theories (4.2) is incompatible with this limit, since both Λ and $\tilde{\Lambda}$ go to zero.

Thus, the $r \rightarrow 0$ limit does not commute with the infrared limit at fixed coupling needed in the duality.

We can take the limit in which we keep Λ , $\tilde{\Lambda}$ and r fixed and look at energies $E \ll \Lambda, \tilde{\Lambda}, \frac{1}{r}$. In this limit, we are in the infrared, at fixed coupling but with a finite radius. However, this is not a problem since the effective theory at low energy doesn't see the compactified dimension. As a result, the dynamics of the theory is effectively three dimensional.

The theories we find with this procedure have few properties that distinguish them from purely three-dimensional theories. The scalar associated with the holonomy of the gauge field along the compactified direction is periodic, because

$$P\left(\exp\left(i \oint A_3\right)\right) \quad (4.4)$$

is gauge invariant.

As a result the scalar of the compactified theory is compact whereas the three dimensional one is not. Four dimensional theories on the circle have an additional non-perturbative superpotential generated by a Kaluza-Klein monopole. This particular type of instanton/monopole configurations¹ of the gauge field is generated through a non-periodic gauge transformations on an instanton configuration of the gauge field. Even though the transformation is not periodic around the circle, the gauge field obtained acting with it remains periodic. For this reason it is associated to a different topological sector with respect to standard instanton/monopole configurations [27].

The generated superpotential reads

$$W = \eta Y_{low} \quad (4.5)$$

where $\eta = \Lambda^b$ and Y_{low} is the Coulomb branch coordinate we defined in (3.10). Theories obtained with this method are dual to each other and they differ from

¹Using this expression we refer to the fact that 't Hooft/Polyakov monopoles in four dimension can be interpreted as three-dimensional instantons after ignoring the time dimension.

truly three-dimensional theories for the reasons we explained above. For example, the introduction of the η superpotential breaks the axial symmetry that is anomalous in four dimensions, but is allowed in three-dimensional theories.

After these considerations we would like to flow from these dualities with finite radius r to truly three-dimensional dualities, i.e. dualities for theories well-defined at high energies. The compactness of the Coulomb branch is not really a problem since for $SU(N)$ gauge theories the η superpotential lifts completely the Coulomb branch together with the Affleck-Harvey-Witten superpotential (3.22). Regarding the η superpotential, in the case we will analyse it is possible to find monopole operators Y_{high} , well-defined at high energies, that flow to the Coulomb branch coordinates Y_{low} at low energies. Using these operators it is possible to define the theories in the ultraviolet, thus turning the dualities we find by reduction as standalone three-dimensional dualities.

4.2 Dimensional reduction of $SU(N_c)$ Seiberg duality

We introduced Seiberg duality in four dimensions in section 2.2 but its analog in three dimensions was discovered only by the procedure of dimensional reduction that we will introduce more precisely in this section.

The superpotential that is generated from four dimensional compactified theories is given by the sum of the AHW superpotential (3.21) and the η superpotential (4.5) and together they lift the Coulomb branch completely.

Comparison of moduli spaces

From the previous sections we know that three-dimensional theories perturbed by ηY should be the same at low energies as four dimensional theories on the circle. From the four dimensional duality we know that the compactified theory is dual to a four dimensional magnetic theory. Such theory can be mapped into a three dimensional theory by the same arguments we used for the electric theory. We will compare the moduli spaces between four and three dimensional theories to see if this argument is valid in this case.

For $N_f = N_c - 1$ the four dimensional theory does not admit a vacuum but the unperturbed three dimensional theory has a moduli space subject to the constraint (3.25). Adding the η superpotential result in a theory without a stable vacuum, as the four dimensional theory.

For $N_f = N_c$ the four dimensional theory has an effective description that can be implemented by a Lagrange multiplier that reads

$$W_{3d}^{S^1} = \lambda \left(B\tilde{B} - \det(M) + \Lambda^{2N_c} \right) = \lambda \left(B\tilde{B} - \det(M) + \eta \right) \quad (4.6)$$

since $b = 3N_c - N_f = 2N_c$ for these particular values.

The three-dimensional theory with the additional η superpotential has an effective

description given by

$$W_{3d} = Y \left(B\tilde{B} - \det(M) + \eta \right) \quad (4.7)$$

which suggests the identification between λ and Y .

For $N_f = N_c + 1$ it can be demonstrated that the moduli spaces match but the situation is a little more involved and we refer to [21] for a more complete discussion.

4.2.1 Flow to a pure three-dimensional duality

We can flow to a three-dimensional duality without η superpotential by performing a real mass flow on the theory. We give a large real mass to a flavour of quark and then integrate them out. This process will give us a duality between theories in three dimensions without the *eta* superpotential, obtaining the already known three dimensional dualities.

Let's consider a three dimensional theory with η superpotential and with $N_f + 1$ flavours and let's give a real mass m to the last flavour. We will set in the limit in which $m \rightarrow \infty$ in order to integrate out the last flavour. This can be achieved by giving expectation values to the fields associated to the diagonal $SU(N_f + 1) \times U(1)_B$ flavour symmetry given by

$$\begin{aligned} \text{diag}(0, \dots, m) &= \text{diag}(m_B - M, \dots, m = m_B + N_f M) \\ \text{with } m_B = M &\rightarrow m = M(N_f + 1) \end{aligned} \quad (4.8)$$

where M is associated to the diagonal $SU(N_f + 1)$ and m_B to $U(1)_B$.

The real masses are easily mapped to the dual theory by considering the charges of the quarks under the global symmetries in question (cfr. tables (2.16) and (2.45)).

$$M \rightarrow -M \quad m_B \rightarrow \frac{N_c}{N_f - N_c + 1} m_B \quad (4.9)$$

As a result the first N_f flavours get a mass \tilde{m}_1 and the last one a mass \tilde{m}_2

$$\tilde{m}_1 = \frac{\tilde{m}}{N_f - N_c + 1} \quad \tilde{m}_2 = \frac{\tilde{m}(N_c - N_f)}{N_f - N_c + 1} \quad (4.10)$$

In the electric theory we will be interested in configurations that remain at a finite distance from the origin in the Coulomb branch in the limit $m \rightarrow 0$, i.e. with the VEV of σ_i finite. For these types of vacua, the last flavour is massive and can be integrated out at low energies, resulting in an effective $SU(N_c)$ theory with N_f flavours. Since we integrated out an equal number of left and right fermions, no Chern-Simons terms are generated [23].

The monopole operator Y_{high} is related to the low-energy coordinate Y_{low} by the relation $Y_{low} = Y_{high}/m$, where m is the complex mass of quark [21]. Since the real mass is given by a component of a vector multiplet, the superpotential $W = \eta Y_{high}$ vanishes, since we didn't assign any complex mass to the quark.

As a result, the electric theory we obtain is a $SU(N_c)$ gauge theory with N_f massless flavours and no η -superpotential. The absence of the η -superpotential results in a theory with axial symmetry, since it was the only term that was breaking it. The charges of the fields are given by

	$SU(N_c)$	$U(1)_R$	$U(1)_A$	$U(1)_B$	$SU(N_f)_L$	$SU(N_f)_R$
Q	N_c	1	-1	1	\bar{N}_f	1
\bar{Q}	\bar{N}_c	1	-1	-1	1	N_f
Y	1	$2(N_c - N_f - 1)$	$-2N_f$	0	1	1

(4.11)

The magnetic theory does not have vacuum at the origin of the Coulomb branch since each flavour acquire masses proportional to m . The vacuum configuration with the great number of massless quarks is given by following the vacuum expectation value of the dual gluon $\tilde{\sigma}$

$$\tilde{\sigma} = \text{diag} \left(\overbrace{-\tilde{m}_1, \dots, -\tilde{m}_1}^{N_f - N_c \text{ values}}, -\tilde{m}_2 \right) \quad (4.12)$$

Note that this expectation value is traceless, as it should be.

This vacuum breaks the gauge symmetry $SU(N_f - N_c + 1) \rightarrow SU(N_f - N_c) \times U(1)$. We can view it as $U(N_f - N_c)$ with quarks in the representations

component	quark	$U(N_f - N_c)$
$1, \dots, N_f$	q	$(N_f - N_c)_1$
$1, \dots, N_f$	\tilde{q}	$(N_f - N_c)_1$
$N_f + 1$	p	$1_{-(N_f - N_c)}$
$N_f + 1$	\tilde{p}	$1_{(N_f - N_c)}$

(4.13)

The mesons' components created from quarks with the same real mass remain light, since left and right quarks have opposite charges and global symmetries. Thus, the massless mesons are a $N_f \times N_f$ matrix, that can be identified with the mesons M of the electric theory, and a single singlet field $M_{N_f+1}^{N_f+1}$ which we will call Y , since we will identify later with the monopole operator Y .

The off-diagonal components, i.e $M_{N_f+1}^i$ and $M_i^{N_f+1}$ with $i = 1, \dots, N_f$ have a mass proportional to \hat{m} and can be integrated out.

The η superpotential can be written in terms of $U(N_f - N_c)$ Coulomb branch variables that we defined in (3.27). Since the gauge group comes from the breaking of $SU(N_f - N_c + 1)$ the superpotential is written as

$$W = \tilde{\eta} \tilde{V}_- \quad (4.14)$$

In addition to this superpotential, there's a AHW term [22] in the superpotential, related to the breaking of the gauge group from $SU(N_f - N_c + 1)$ to $SU(N_f - N_c) \times U(1)$ which is given by a term

$$W = \tilde{V}_+ \quad (4.15)$$

The complete superpotential of the magnetic theory is given by

$$W_{mag} = M q\tilde{q} + Y p\tilde{p} + \tilde{\eta}\tilde{V}_- + \tilde{V}_+ \quad (4.16)$$

At this point, $\tilde{\eta}$ does not play any role anymore and it can be absorbed in a redefinition of \tilde{V}_- . The Coulomb branch of this theory is completely lifted by the last two terms of the superpotential.

The global symmetries of the theory consist of the $SU(N_f)_L \times SU(N_f)_R \times U(1)_R$ symmetries inherited from four dimensions, the topological symmetry $U(1)_J$ associated to the abelian factor in the gauge group and two abelian factors given by $U(1)_B$ and $U(1)_A$, that are not broken by the superpotential.

From the matching of the gauge invariant operators between the two theories we can fix most of the quantum numbers. The baryons of the electric theory are matched in the magnetic theory to $b = q^{N_f - N_c} p$ and $\tilde{b} = \tilde{q}^{N_f - N_c} \tilde{p}$.

The $U(1)_B$ symmetry mixes with abelian term of the gauge group and it can be chosen arbitrarily.

The charges are the following

	$U(N_f - N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_R$
q	$(N_f - N_c)_1$	$\overline{N_f}$	1	0	-1	1
\tilde{q}	$(\overline{N_f - N_c})_{-1}$	1	$\overline{N_f}$	0	-1	1
p	$1_{-(N_f - N_c)}$	1	1	N_c	N_f	$-(N_f - N_c)$
\tilde{p}	$1_{(N_f - N_c)}$	1	1	$-N_c$	N_f	$-(N_f - N_c)$
M	1	1	1	0	2	0
Y	1	1	1	0	$-2N_f$	$2(N_f - N_c + 1)$
\tilde{V}_\pm	1	1	1	0	0	2

(4.17)

The meson field Y has the same quantum numbers of the Y field in the electric and for this reason is natural to identify them. The quantum numbers of V_\pm are calculated by counting zero modes and the fact that are consistent with the superpotential (4.16) is a check of the result.

As a result of this process we found a three-dimensional duality that wasn't known as a standalone duality before the method of dimensional reduction was discovered in [21]. The duality can be checked by the matching of the partition functions between the two theories. We will focus on this approach in the next chapters.

As an additional check of this duality we can use it to reduce to the Aharony duality we introduced in section 3.2. Since it is a duality involving $U(N)$ gauge theories, we can achieve this by gauging the baryonic symmetry, since it has opposite charges for left and right quarks.

The Coulomb branch coordinates are now given by the independent operators V_\pm . The $U(N_c)$ theory has an additional global symmetry $U(1)_J$ associated to the $U(1)$ factor in the gauge group. The duality maps the electric $U(N_c)$ theory with N_f flavours with superpotential

$$W_{el} = \eta V_+ V_- \quad (4.18)$$

to a $U(N_f - N_c)$ theory with N_f flavours and mesons M with

$$W_{mag} = \tilde{\eta} Y_+ Y_- + M q \tilde{q} \quad (4.19)$$

Both theories have a one-dimensional Coulomb branch which is not lifted by the superpotential, since it only affects the $SU(N)$ factor of the group and a matching between the two is possible.

The same procedure can be applied to the duality we found without the η superpotential. The steps on the electric theory are similar to the $SU(N_c)$ case we described previously, while the charges of the magnetic theory we used in (4.17) was chosen in such a way that the only fields charged under the baryonic symmetry were p, \tilde{p} . As a result, the new sector of the theory is a $U(1)$ gauge theory with only one flavour. Its low-energy description is given by a superpotential, relating its monopole operators V_+, V_- with the meson $N = p\tilde{p}$ by

$$W = -V_+ V_- N \quad (4.20)$$

The superpotential we obtained by the reduction (4.16) contains a term given by $W = YN$. The equation of motion of N sets $Y = \tilde{V}_+ \tilde{V}_-$. Integrating out the massive fields the monopole operators \hat{X}_\pm of the low-energy theory $U(N_f - N_c)$ can be related to the high-energy monopoles Y_\pm of $U(N_f - N_c) \times U(1)_B$ by the relation [21]

$$Y_\pm \simeq \hat{X}_\pm \tilde{V}_\mp \quad (4.21)$$

As a result the superpotential ² is given by

$$W_{mag} = M q \tilde{q} + \hat{X}_- \tilde{V}_+ + \hat{X}_+ \tilde{V}_- \quad (4.22)$$

which is the same superpotential of the magnetic theory in Aharony duality, after the identification of the singlets \tilde{V}_\pm with the fields V_\pm of the electric theory.

4.3 Reduction of KSS duality

4.3.1 $U(N_c)$ duality

We will first focus on the reduction of KSS duality introduced in section 2.3 but with $U(N_c)$ gauge group which is obtained by gauging the baryonic $U(1)_B$ symmetry. The dynamics of the $U(1)$ factor in the gauge group is infrared free so it does not affect the duality.

The reduction of the theory to $\mathbb{S}^3 \times \mathbb{S}^1$ features a η superpotential that is generated by Kaluza-Klein monopoles as in the previous section.

Because of the superpotential $\text{Tr } X^{k+1}$ there are $2k$ unlifted directions in the moduli space that are parametrized by $t_{i,\pm}$ as in (3.35). The counting of the fermion

² We rescaled the field Y_- by a factor $\tilde{\eta}$ since it does not play any role in the duality anymore.

zero modes for the KK-monopoles shows that they generate a superpotential [28]

$$W_\eta = \eta \sum_{j=0}^{k-1} t_{j,+} t_{k-1-j,-} \quad (4.23)$$

In the magnetic theory a similar superpotential is generated, involving magnetic monopoles $\tilde{t}_{i,\pm}$ of the dual theory. The addition of these superpotential guarantees that the duality is consistent with the compactification.

Since we are interested in the reduction to the Kim-Park duality (section 3.3) without η -superpotential, we will add real masses to some quarks as we did in section 4.2.1.

Since the baryonic symmetry is gauged, we need to start from $N_f + 2$ flavours and assign masses (m, \tilde{m}) associated to the background gauging of the $SU(N_f + 2)_L \times SU(N_f + 2)_R$ global symmetry

$$m_{el} = \text{diag} \left(\underbrace{m_A, \dots, m_A}_{N_f}, M - \frac{m_A N_f}{2}, -M + \frac{m_A N_f}{2} \right) \quad (4.24)$$

$$\tilde{m}_{el} = \text{diag} \left(\underbrace{m_A, \dots, m_A}_{N_f}, -M + \frac{m_A N_f}{2}, M - \frac{m_A N_f}{2} \right) \quad (4.25)$$

This mass assignment breaks the symmetry group to $SU(N_f)_L \times SU(N_f)_R \times U(1)_A$, where $U(1)_A$ is the axial symmetry that the η -superpotential breaks. However, since we are in the limit in which M is large, the η -superpotential vanish in this flow since the quarks don't have complex masses as in [21]. As a result, the theory flows to the electric theory of Kim-Park duality.

The magnetic theory is now a $U(k(N_f + 2) - N_c)$ gauge theory with $N_f + 2$ flavours. The real masses of the electric theory are easily mapped to the magnetic theory by comparing the global symmetries

$$m_{mag} = \text{diag} \left(\underbrace{m_A, \dots, m_A}_{N_f}, M - \frac{m_A N_f}{2}, -M - \frac{m_A N_f}{2} \right) \quad (4.26)$$

$$\tilde{m}_{mag} = \text{diag} \left(\underbrace{m_A, \dots, m_A}_{N_f}, -M - \frac{m_A N_f}{2}, M - \frac{m_A N_f}{2} \right) \quad (4.27)$$

The magnetic theory can be weakly perturbed by a polynomial superpotential in the adjoint matter field

$$W = \sum_{j=2}^{k+1} s_j \text{Tr } \tilde{X}^j \quad (4.28)$$

which in this case doesn't contain a term proportional to $\text{Tr } \tilde{X}$ as in the $SU(N)$ case since it would force \tilde{X} to be traceless.

The superpotential triggers a breaking of the gauge group

$$U(k(N_f + 2) - N_c) \longrightarrow U(r_1) \times \cdots \times U(r_k) \quad \sum_{j=1}^k r_i = k(N_f + 2) - N_c \quad (4.29)$$

As in section 2.3.1, in every vacuum the adjoint matter is massive and is integrated out, resulting in k different SQCD sectors without adjoint matter. The vacuum configuration for the adjoint scalar such that we have the largest number of massless particles is

$$\tilde{\sigma}_{U(r_i)} = \text{diag} (0, \dots, -M, M) \quad (4.30)$$

that results in the breaking pattern

$$U(r_1) \times \dots \times U(r_k) \longrightarrow (U(r_1 - 2) \times U(1)^2) \times \cdots \times (U(r_k - 2) \times U(1)^2) \quad (4.31)$$

The fields that remain massless in this vacuum are the following

- (q_j^i, \tilde{q}_j^i) dual quarks with $i = 1, \dots, k$ and $j = 1, \dots, N_f$ which corresponds to the first N_f flavours of quarks for every $U(r_i - 2)$ sector that remain massless
- (p_a^i, \tilde{p}_a^i) with $a = 1, 2$. They are the last two flavours of quarks charged under one of the two $U(1)$ sector for each value of i
- $(M_j)_i^i$ mesons with $j = 0, \dots, k - 1$ coming from the first N_f flavours of electric quarks.
- $(M_j)^a$ mesons associated to $M_{N_f+1}^{N_f+1}$ and $M_{N_f+2}^{N_f+2}$

and the other fields obtain a large mass in this limit.

We can define the following composite operators out of these fields where for \tilde{X} we mean its value in the vacuum since it is massive.

$$(N_j)^i = q_j^i \tilde{X}^j \tilde{q}_j^i \quad (4.32)$$

$$(\hat{N}_j)_a^i = p_a^i \tilde{X}^j \tilde{p}_a^i \quad (4.33)$$

The mesons' superpotential term can be rewritten and is given by

$$W = \sum_{j=0}^{k-1} \sum_{i=1}^k M_j N_{k-j-1}^i + \sum_{a=1}^2 \sum_{i=1}^k \sum_{j=0}^{k-1} M_j^a (\hat{N}_j)_a^i \quad (4.34)$$

The two $U(1)$ sectors can be given an effective description using (3.18) which results in

$$W_{U(1)} = \sum_{a=1,2} \sum_{i=1}^k (\hat{N}_0)_a^i v_+^{i,a} v_-^{i,a} \quad (4.35)$$

where $v_{\pm}^{i,a}$ are the Coulomb branch coordinates of the i -th $U(1)$ sector. The breaking of each gauge group factor from $U(r_i) \rightarrow U(r_i - 2) \times U(1)^2$ generates three Affleck-Harvey-Witten terms in the superpotential

$$W_{AHW} = \sum_{i=1}^k \left(\tilde{V}_{i,+} v_{-}^{i,1} + \tilde{V}_{i,-} v_{+}^{i,2} \right) \quad (4.36)$$

where $V_{i,\pm}$ are the Coulomb branch coordinates for the $U(r_i - 2)$ sectors.

The equations of motion set the terms with $(\hat{N}_j)_a^i$. After sending the mass M to infinity, we can weakly switch off the deformation in the adjoint field. As a result, the $U(r_i - 2)$ factors recombine to $U(kN_f - N_c)$ with adjoint matter Y . While removing the deformation, the $2k$ $U(1)$ factors become $U(k) \times U(k)$ each with one flavour and one adjoint matter field. Such a theory should not have a vacuum because of the condition (2.66) but the additional terms in the superpotential should modify this condition. We assume that this enhancement to $U(k)$ does not modify the results and we will see in the next chapter using an independent argument on the partition function that our assumption is indeed correct.

The Coulomb branch coordinates of the $U(r_i - 2)$ terms give the Coulomb branch coordinates of the gauge group $U(kN_f - N_c)$ while the coordinates of the $U(1)^2$ factors are identified with the chiral fields $t_{j,\pm}$ (3.37) that are mapped to the Coulomb branch coordinates of the electric theory. The superpotential is then given by

$$W = \text{Tr } \tilde{X}^{k+1} + \sum_{j=0}^{k-1} M_j q Y^{k-j-1} \tilde{q} + \sum_{j=0}^{k-1} \left(t_{j,+} \tilde{t}_{k-1-j,-} + t v_{j,-} \tilde{t}_{k-1-j,+} \right) \quad (4.37)$$

which is the same as the one appearing in the magnetic theory of Kim-Park duality.

4.3.2 $SU(N_c)$ duality

This duality first appeared in [29] and it was obtained from the duality of the previous section by ungauging the $U(1)$ factor. In order to derive the duality with $SU(N_c)$ gauge group we do not gauge the baryonic symmetry as in the previous case and we start directly from KSS duality in four dimensions.

The Coulomb branch of this theory is different from a $U(N_c)$ theory and the monopole operators are now given by [28]

$$Y_i \sim \exp \left(\frac{\Phi_i - \Phi_{i+1}}{g^2} \right) \quad Y = \prod_i Y_i \quad (4.38)$$

$$V_{i,j} \sim (X_{11})^i (X_{N_c N_c})^j Y \quad (4.39)$$

These monopole operators are related to the $U(N_c)$ ones by the relations

$$V = V_+ V_- \quad V_{i,j} = V_{i,+} V_{-,j} \quad (4.40)$$

After the compactification on the circle, Kaluza-Klein monopoles generate the terms [28]

$$W_{\eta,el} = \sum_{j=0}^{k-1} \eta V_{j,k-1-j} \quad W_{\tilde{\eta},mag} = \sum_{j=0}^{k-1} \tilde{\eta} \tilde{V}_{j,k-1-j} \quad (4.41)$$

which can be verified by the counting of the zero modes.

The electric theory is the reduction of the electric theory in four dimensions with the addition of the η superpotential defined above. The same is true for the magnetic theory too.

As in the previous cases, we can flow to a duality without these terms in the superpotential by a suitable assignment of real masses.

We start our reduction with $N_f + 1$ flavours. In the electric theory we assign the following values for real masses associated to the $SU(N_f + 1)_L \times SU(N_f + 1)_R \times U(1)_B$ global symmetry. The value of the diverging mass associated respectively to the flavour and baryonic symmetry M, M_B are chosen in order to break the global symmetry group to $SU(N_f)_L \times SU(N_f)_R \times U(1)_B \times U(1)_A$. This requirement imposes the condition $M = M_B$

The real mass of the left quarks are

$$m_{el} = \begin{pmatrix} (M_B - M) + m_A & & & \\ & \ddots & & \\ & & (M_B - M) + m_A & \\ & & & (M_B + N_f M) - m_A N_f \end{pmatrix} \quad (4.42)$$

$$= \begin{pmatrix} m_A & & & \\ & \ddots & & \\ & & m_A & \\ & & & -m_A N_f + m \end{pmatrix} \quad m = M_B + N_f M \quad (4.43)$$

$$(4.44)$$

The real masses of the right quark \tilde{Q}

$$\tilde{m}_{el} = \begin{pmatrix} M - M_B + m_A & & & \\ & \ddots & & \\ & & M - M_B + m_A & \\ & & & -M_B - N_f M - m_A N_f \end{pmatrix} \quad (4.45)$$

$$= \begin{pmatrix} m_A & & & \\ & \ddots & & \\ & & m_A & \\ & & & -m - m_A N_f \end{pmatrix} \quad m = M_B + N_f M \quad (4.46)$$

By comparison of the charges of the fields under the global symmetries, we can map the masses to the magnetic theory

$$\tilde{M} = -M \quad \tilde{M}_B \rightarrow \frac{N_c}{k(N_f + 1) - N_c} M_B \quad \tilde{m}_A = m_A \quad (4.47)$$

which results in

$$m_{mag} = \begin{pmatrix} m_1 - m_A & & & \\ & \ddots & & \\ & & m_1 - m_A & \\ & & & m_2 + m_A N_f \end{pmatrix} \quad (4.48)$$

$$\tilde{m}_{mag} = \begin{pmatrix} -m_1 - m_A & & & \\ & \ddots & & \\ & & -m_1 - m_A & \\ & & & -m_2 + m_A N_f \end{pmatrix} \quad (4.49)$$

where we defined

$$m_1 = \tilde{M}_B - \tilde{M} = \frac{k}{k(N_f + 1) - N_c} m \quad (4.50)$$

$$m_2 = \tilde{M}_B + N_f \tilde{M} = -\frac{kN_f - N_c}{k(N_f + 1) - N_c} m \quad (4.51)$$

The global symmetries in the magnetic theory are broken in the same way as in the electric one.

We can introduce a deformation to the superpotential for both theories

$$W_{el} = \sum_{j=1}^k s_j \text{Tr } X^j \quad W_{mag} = \sum_{j=1}^k \tilde{s}_j \text{Tr } Y^j \quad (4.52)$$

Where the terms proportional to $\text{Tr } X, \text{Tr } Y$ are Lagrange multipliers to enforce the traceless of X and Y .

By giving a large value to m we flow to a theory without η superpotential, as in the previous cases. In the electric side, the deformation breaks the gauge group $SU(N_c) \rightarrow SU(i_1) \times \cdots \times SU(i_k) \times U(1)^{k-1}$ with $\sum_j i_j = N_c$.

Taking the vacuum expectation value for σ at the origin, the last quark flavour gets integrated out and we find a theory with N_f flavours and no η superpotential. In the magnetic side, the perturbation breaks the gauge group in a similar way, from $SU(k(N_f + 1) - N_c)$ to

$$U(j_1) \times \cdots \times U(j_k)/U(1) \simeq SU(j_1) \times \cdots \times SU(j_k) \times U(1)^k/U(1) \quad (4.53)$$

$$\simeq SU(j_1) \times \cdots \times SU(j_k) \times U(1)^{k-1} \quad (4.54)$$

$$\text{with } \sum_l j_l = k(N_f + 1) - N_c \quad (4.55)$$

However, since each quark has a large real mass, the vacuum cannot be chosen at the origin and we need to choose the vacuum in order to have the largest number of massless fields. As a result, the gauge group is broken further into

$$SU(i_1 - 1) \times \cdots \times SU(i_k - 1) \times U(1)^k \times U(1)^{k-1} \quad (4.56)$$

since the vacuum of $\tilde{\sigma}$ in every $SU(i_k)$ sector is given by

$$\tilde{\sigma}_{i_1} = \begin{pmatrix} -m_1 & & & \\ & \ddots & & \\ & & -m_1 & \\ & & & -m_2 \end{pmatrix}, \dots, \tilde{\sigma}_{i_k} = \begin{pmatrix} -m_1 & & & \\ & \ddots & & \\ & & -m_1 & \\ & & & -m_2 \end{pmatrix} \quad (4.57)$$

The $U(1)^{k-1}$ factor is associated to the breaking of the group from the vacuum expectation values of Y while the $U(1)^k$ factor results from the breaking caused by the vacuum choice of $\tilde{\sigma}$.

Before doing so, we are going to use $3D\mathcal{N} = 2$ mirror symmetry [23] in the $U(1)^{k-1}$ sector of the deformed theory. As a result, this sector will be described by a $U(1)$ gauge theory with k flavours (b_i, \tilde{b}_i) .

We need to stress that we used mirror symmetry applied to the $U(1)^{k-1}$ gauge sector in the deformed theory but after switching off the deformation (4.52), the gauge group becomes $U(k)$ and a mirror dual is not known.

We assume that this enhancement to $U(k)$ in the undeformed theory does not modify the results we obtained. We will provide an independent method to reduce the duality through the partition function which does not rely on the deformation of the superpotential. This method will yield the same result we found using this assumption.

In order to obtain Kim-Park duality, we will need to switch off the deformation on both sides of the duality.

In the electric side, the gauge group recovers the original $SU(N_c)$ and we find the electric theory of Kim-Park duality, without η superpotential. The charges of the fields are given by

Fields	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
Q	N_f	0	N_c	1	0	Δ_Q
\tilde{Q}	0	$\overline{N_f}$	$-N_c$	1	0	$\Delta_{\tilde{Q}}$
X	0	0	0	0	0	Δ_X

(4.58)

In the magnetic side, we recover $SU(kN_f - N_c) \times U(1) \times U(1)_{\text{mirror}} \simeq U(kN_f - N_c) \times U(1)_{\text{mirror}}$ with the following massless fields

- $U(kN_f - N_c)$ quarks in the (anti)fundamental representation (q, \tilde{q})
- $U(kN_f - N_c)$ adjoint matter Y
- $U(kN_f - N_c)$ singlets M_j with $N_f \times N_f$ flavours indices.

- $U(1)$ quarks with k flavours (b, \tilde{b}) , obtained by mirror symmetry

The quantum numbers of these fields are obtained by the matching of the mesons and baryons.

The charges of the fields are the following

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
q	$\overline{N_f}$	0	0	-1	0	$\Delta_Y - \Delta_Q$
\tilde{q}	0	N_f	0	-1	0	$\Delta_Y - \Delta_Q$
Y	0	0	0	0	0	Δ_Y
M_j	N_f	$\overline{N_f}$	0	2	0	$2\Delta_Q + j\Delta_Y$
b_j	0	0	0	$-N_f$	1	$N_f(1 - \Delta_Q) + \Delta_Y(-N_c + j + 1)$
\tilde{b}_j	0	0	0	$-N_f$	-1	$N_f(1 - \Delta_Q) + \Delta_Y(-N_c + j + 1)$
$\tilde{v}_{j,\pm}$	1	1	0	N_f	± 1	$-(1 - \Delta_Q)N_f + \Delta_Y(N_c + 1 + j)$

(4.59)

where $\tilde{v}_{i,\pm}$ is one of the two Coulomb branch coordinates of the $U(kN_f - N_c)$ gauge group.

Note that the fields (b_i, \tilde{b}_i) are charged under the topological symmetry and have the right quantum numbers to couple with the monopole operators $\tilde{v}_{i,\pm}$.

The baryonic symmetry can mix with the $U(1)$ factor in the $U(kN_f - N_c)$ gauge group and as a result its definition is ambiguous. We chose to remove this ambiguity by leaving all the fields uncharged under it. Another possibility is to give opposite charges to the quarks (q, \tilde{q}) .

The η superpotential can be rewritten using monopole operators at high energy through the identification [28]

$$\tilde{V}_{j,k-1-j} = b_j \tilde{v}_{k-1-j,-} \quad (4.60)$$

As in the previous cases, there is a Affleck-Harvey-Witten superpotential associated to the gauge symmetry breaking $SU(k(N_f + 1) - N_c) \rightarrow U(kN_f - N_c) \times U(1)^{mirror}$ given by

$$W_{AHW} = \sum_{j=0}^{k-1} \tilde{b}_{j+1} \tilde{v}_{k-1-j,+} \quad (4.61)$$

Adding all these terms we obtain the superpotential of the theory which reads

$$W_{mag} = \text{Tr } Y^{k+1} + \sum_{j=0}^{k-1} M_j \tilde{q} Y^{k-1-j} q + \sum_{j=0}^{k-1} (b_j \tilde{v}_{k-j-1,-} + \tilde{b}_j \tilde{v}_{k-j-1,+}) \quad (4.62)$$

which is consistent with what was found with ungauging technique from the $U(N_c)$ duality in [29].

Chapter 5

Superconformal index and partition functions

5.1 Superconformal index

In superconformal field theories, the superconformal index is a quantity that counts the number of short multiplets in the theory, which satisfy a BPS bound. The scaling dimensions of these states saturate a unitarity bound.

For $\mathcal{N} = 4$ field theories it was first introduced in [30] and it was later modified by Romelsberger for $\mathcal{N} = 1$ field theories in [31].

The superconformal index can be introduced as a generalization of the Witten index, which is defined as

$$I = \text{Tr} \left[(-1)^F e^{-\beta E} \right] \quad (5.1)$$

where F is the fermion number and E the energy of the state.

The exponential term in the energy can be seen as a regulator, otherwise the counting would not be well defined. However, the energy E can be substituted with any operator with positive eigenvalues that commutes with the supercharges. In order to resolve the degeneracies other operators that commute with the supercharges can be added to the definition of the index.

We are interested in four dimensional superconformal field theories which are naturally quantized in radial quantization on $S^3 \times \mathbb{R}$. As a result, the isometry group is now $SU(2)_L \times SU(2)_R \times \mathbb{R}$ and the eight supercharges split into doublets of $SU(2)_L$ for Q_α and of $SU(2)_R$ for S_α .

We can pick one of the supercharges, e.g. Q_1 , and from the superconformal algebra we have the relation

$$\{Q_1, Q_1^\dagger\} = H - \frac{3}{2}R - 2J_1 = \Delta \quad (5.2)$$

where H is the Hamiltonian in radial quantization, R is the R-charge generator and J_1 is one of the generators of $SU(2)_L$. However, in a free theory Δ has an

infinite of states with zero eigenvalue. For this reason the operator used as a regulator is [31]

$$\Xi = H - \frac{1}{2}R \geq \frac{2}{3}H \quad (5.3)$$

which damps as well as the Hamiltonian.

As we said before, we can add other terms in order to differentiate the various states. Such terms are given by the Cartan generators J_1, J_2 of the $SU(2)_L \times SU(2)_R$ isometry of the three-sphere and by the generators e_a of the internal symmetry group.

The superconformal index on the sphere $S^3 \times S^1$ is then defined as [32]

$$i(x, h_a) = \text{Tr} \left[(-1)^F e^{-\mu \Xi} x^{2J_2} \prod_a h_a^{e_a} \right] \quad (5.4)$$

$$= \text{Tr} \left[(-1)^F t^{\Delta+2J_1-R} x^{2J_2} \prod_i h_a^{e_a} \right] \quad (5.5)$$

where we defined $t = e^{-\mu}$. With a change of variables, the superconformal index can be written as

$$i(p, q, h_a) = \text{Tr} \left[(-1)^F (pq)^{\frac{\Delta}{2}} p^{J_1+J_2-\frac{R}{2}} q^{J_1-J_2-\frac{R}{2}} \prod_a u_a^{e_a} \right] \quad (5.6)$$

where p, q are defined by

$$p = tx \quad q = tx^{-1} \quad (5.7)$$

The values of the fugacities p, q must satisfy the following conditions in order for the index to be real and well-defined.

$$\text{Im}(pq) = 0 \quad |p/q| = 1 \quad |pq| < 1 \quad (5.8)$$

The superconformal index receives contribution only from states with $\Delta = 0$, since $J_1 \pm J_2 - \frac{R}{2}$ and the internal generators commute with Δ . The superconformal index can be calculated in two steps. First, we need to obtain the index on *single particle states*.

The single particle index for chiral multiples Φ_i with R-charge r_i , with flavour symmetry group F_i and gauge group G_i reads [33]

$$i_\Phi(t, x, h, g) = \sum_i \frac{t^{r_i} \chi_{F_i}(h) \chi_{G_i}(z) - t^{2-r_i} \chi_{\bar{F}_i}(h) \chi_{\bar{G}_i}(z)}{(1-tx)(1-tx^{-1})} = \quad (5.9)$$

$$= \sum_i \frac{(pq)^{\frac{r_i}{2}} \chi_{F_i}(h) \chi_{G_i}(z) - (pq)^{1-\frac{r_i}{2}} \chi_{\bar{F}_i}(h) \chi_{\bar{G}_i}(z)}{(1-p)(1-q)} \quad (5.10)$$

where h and z are the chemical potential for the global and gauge symmetry group respectively. $\chi_{F_i}(h)$ and $\chi_{G_i}(z)$ are the characters of the representation of Φ_i .

The index for a vector superfield in the adjoint representation of a gauge group G is given by [33]

$$i_V(t, x, g) = \frac{2t^2 - t(x + x^{-1})}{(1 - tx)(1 - tx^{-1})} \chi_{adj}(z) = \frac{2(pq) - (p + q)}{(1 - p)(1 - q)} \chi_{adj}(z) \quad (5.11)$$

The index on the single particle states for the complete theory is given by the sum of indices for every field. Then, the superconformal index can be calculated by taking the Plethystic exponential [34] of the full single particle index

$$I(t, x, h) = \int_G d\mu(g) \exp \left(\sum_{n=1}^{\infty} i(t^n, x^n, h^n, z^n) \right) \quad (5.12)$$

where $d\mu(g)$ is a G invariant measure.

The definition of the superconformal index can be extended to the manifold $S_b^3 \times S^1$, where S_b^3 is the squashed three-sphere whose isometry group is only $U(1)_L \times U(1)_R$ [35]. The squashed sphere is defined by considering the metric

$$ds^2 = l^2(dx_0^2 + dx_1^2) + \bar{l}^2(dx_2^2 + dx_3^2) \quad (5.13)$$

$$\text{with} \quad x_0^2 + x_1^2 + x_2^2 + x_3^2 = 1 \quad (5.14)$$

With the change of coordinates

$$x_0 = \cos \theta \cos \phi \quad (5.15)$$

$$x_1 = \cos \theta \sin \phi \quad (5.16)$$

$$x_2 = \sin \theta \cos \chi \quad (5.17)$$

$$x_3 = \sin \theta \sin \chi \quad (5.18)$$

we obtain the metric of the squashed sphere with squashing parameter $b = l/\bar{l}$

$$ds^2 = f(\theta)^2 d\theta^2 + l^2 \cos^2 \theta d\phi^2 + \bar{l}^2 \sin^2 \theta d\chi^2 \quad (5.19)$$

$$\text{with} \quad f(\theta) = \sqrt{l^2 \sin^2 \theta + \bar{l}^2 \cos^2 \theta} \quad (5.20)$$

The index on the squashed sphere $S_b^3 \times S^1$ should coincide with the index on the round sphere $S^3 \times S^1$ since they have the same topology and the indices receive contributions from the same BPS states. The indices match up to a rescaling of the fugacities $(p, q) \rightarrow (p^{\frac{1}{a}}, q^{\frac{1}{b}})$ [36] and a factor given by the Casimir energy [37]. The rescaling of the fugacities does not modify the physical content of the index because (p, q) are arbitrary parameters and they still satisfy the conditions (5.8).

An exact calculation of the index can be performed using the following mathematical identities involving the elliptic gamma function Γ_e . The index of a chiral field in general can be written as

$$i_\Phi(p, q, y) = \frac{y - pq/y}{(1 - p)(1 - q)} \quad \text{with} \quad p = tx \quad q = tx^{-1} \quad y = t^R \quad (5.21)$$

where z is the fugacity associated to gauge and/or global symmetries. It can be written as an elliptic gamma function through

$$\exp\left(\sum_{n=1}^{\infty} \frac{1}{n} i_S(p^n, q^n, y^n)\right) = \prod_{j,k \geq 0} \frac{1 - y^{-1} p^{j+1} q^{k+1}}{1 - y p^j q^k} \stackrel{def}{=} \Gamma_e(y; p, q) \quad (5.22)$$

$$\text{where } i_S(p, q, y) = \frac{y - pq/y}{(1-p)(1-q)} \quad (5.23)$$

The contribution to the index of chiral field in the fundamental or antifundamental representation of global and gauge symmetries can be generally written as

$$\Gamma_e\left((pq)^{\frac{R_i}{2}} \prod_a u_a^{e_a}; p, q\right) \quad (5.24)$$

Using the same variables we can write the *single particle index* of a vector multiplet into

$$i_V(p, q) = -\left(\frac{p}{1-p} + \frac{q}{1-q}\right) \quad (5.25)$$

and use the following identities, where z is the chemical potential associated to the gauge group

$$\exp\left(\sum_{n=1}^{\infty} \frac{1}{n} i_V(p^n, q^n)(z^n + z^{-n})\right) = \frac{1}{(1-z)(1-z^{-1})\Gamma_e(z; p, q)\Gamma_e(z^{-1}; p, q)} \quad (5.26)$$

$$\exp\left(\sum_{n=1}^{\infty} \frac{1}{n} i_V(p^n, q^n)\right) = (p; p)(q; q) \quad (5.27)$$

and the *Q-Pochhammer symbol* is defined as

$$(x; p) = \prod_{j \geq 0} (1 - x p^j) \quad (5.28)$$

The contribution of a vector field in the adjoint representation reads

$$(p; p)^{r_G} (q; q)^{r_G} \prod_{1 \leq i < j \leq N_c} \frac{1}{(1 - \frac{z_i}{z_j})(1 - \frac{z_j}{z_i})\Gamma_e(\frac{z_i}{z_j}; p, q)\Gamma_e(\frac{z_j}{z_i}; p, q)} \quad (5.29)$$

The calculation of the superconformal index is now reduced to a integral over the gauge group of products of elliptic gamma functions.

We will provide a more detailed calculation for the electric and magnetic theories of Kutasov-Schwimmer duality in the next chapter.

The equality of the superconformal index for pairs of dual theories can be demonstrated using integral identities of elliptic Gamma functions that were first demonstrated by Rains in [38]. We will use this fact as a starting point in our discussion on the dimensional reduction of dualities to three dimensions.

5.2 Localization

Localization was first introduced by Witten [39] and Nekrasov [40] and later introduced for $\mathcal{N} = 2, 4$ theories on S^4 by Pestun in [41] and then applied to S^3 and S_b^3 for $\mathcal{N} = 2$ theories in [42, 43, 35]. It can be used to calculate exactly the functional integral on a curved manifold.

The basic principle about localization is the following. Suppose that the theory in question admits a *fermionic* symmetry δ which leaves the measure of the path integral invariant and that it squares to a *bosonic* symmetry Δ_B , which can be a Lorentz or gauge transformation.

Consider the following modified partition function, which correspond to the partition function we want to calculate for $t = 0$

$$Z(t) = \int \mathcal{D}\phi e^{-S(\phi) - t(\delta V)} \quad (5.30)$$

where V is a fermionic operator invariant under Δ_B , i.e. $\Delta_B V = 0$.

This partition function is independent of t since

$$\frac{dZ}{dt} = - \int \mathcal{D}\phi \delta V e^{-S(\phi) - t(\delta V)} = - \int \mathcal{D}\phi \delta \left(e^{-S(\phi) - t(\delta V)} \right) = 0 \quad (5.31)$$

Where the last equality holds if the fields decay sufficiently fast at infinity.

Since $Z(t)$ is independent of t we can calculate it at $t = 0$, which is the original partition function or at $t = \infty$, where the integral localizes on the saddle points of the integral if the bosonic part of δV is positive definite.

In three dimensions, these saddle points are parametrized by the values of the scalar field in the vector multiplet and through gauge symmetry the integral can be reduced to the Cartan subalgebra. The saddle point conditions for the other fields set their value on the saddle points to zero.

The partition function receives contribution from the path integral only at one-loop and it can be computed exactly. The one-loop term is given by a determinant of Laplace and Dirac operators for every field appearing in the lagrangian.

$$Z \sim \int [d\sigma] e^{S_{saddle}(\sigma)} \frac{\Delta_\lambda}{\Delta_{A_\mu}} \prod_i \frac{\Delta_{\psi_i}}{\Delta_{\phi_i}} \quad (5.32)$$

The partition function can be written

$$Z(\mu_a, \nu_b) \sim \int [d\sigma] e^{S_{saddle}(\sigma)} Z_{gauge}^{1-loop}(\sigma) Z_{matter}^{1-loop}(\sigma, \mu_a, \nu_b) \quad (5.33)$$

where μ_a, ν_b are the real masses associated to global symmetries for left and right quarks. The one loop contribution for matter fields is given by a hyperbolic gamma function, sometimes called *double-sine* function [35] which depends on the charges of the field under the global and gauge symmetries.

$$Z_{\Phi_i}^{1-loop} = \prod_i \Gamma_h(\omega \Delta_i + \sum_a \mu_a e_a; \omega_1, \omega_2) \quad (5.34)$$

where $\omega_1 = ib$, $\omega_2 = ib^{-1}$ and $\omega = \frac{\omega_1 + \omega_2}{2}$. An overview on the properties of the hyperbolic gamma function can be found in appendix B.

For the vector multiplet the result is similar and since it is in the adjoint representation of the gauge group it is given by

$$Z_V^{1-loop} = \prod_{1 \leq i < j \leq \dim(G)} \frac{1}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \quad (5.35)$$

As a result, the partition function can be calculated by an integral on the Cartan subalgebra of the gauge group of products of hyperbolic gamma functions and exponential factors that are associate to Fayet-Iliopoulos and Chern-Simons terms.

5.3 Reduction of the superconformal index to the partition function

The superconformal index calculated on $S_b^3 \times S^1$ reduces to the partition function of the dimensionally reduced theory on S_b^3 with η superpotential in the limit $S^1 \rightarrow 0$ [44] [45].

A heuristic argument to support this claim is that the superconformal index receives contributions only from BPS states in four dimensions which are in one-to-one correspondence with three dimensional states with non zero eigenvalue of the operators appearing in (5.32).

Moreover, once the BPS condition in four dimensions is dimensionally reduced to three dimensions, it is equivalent to the saddle point conditions of the partition function [36].

In order to obtain the partition function, it is necessary that all the fugacities appearing in the index flow to one [45]. They must be parametrized as function of the radius r of S^1

$$p = e^{2\pi i r \omega_1} \quad q = e^{2\pi i r \omega_2} \quad u_a = e^{2\pi i r \mu_a} \quad z_i = e^{2\pi i r \sigma_i} \quad (5.36)$$

where σ_i is the scalar in the vector multiplet and μ_a are the scalars in the background gauge multiplet that become real masses .

Since the superconformal index is written in terms of elliptic gamma functions, we can use the following identity [46] to perform the limit $r \rightarrow 0$

$$\lim_{r \rightarrow 0^+} \Gamma_e(e^{2\pi i r z}; e^{2\pi i r \omega_1}, e^{2\pi i r \omega_2}) \sim e^{\frac{-i\pi^2}{6r\omega_1\omega_2}(z-\omega)} \Gamma_h(z; \omega_1, \omega_2) \quad (5.37)$$

Using this formula, we can reduce every elliptic gamma function in the index to a hyperbolic gamma function, which is the building block of the partition function in three dimension. The parametrization of the fugacities in (5.36) ensures that the arguments of the hyperbolic gamma functions obtained using this identity match the expressions present in the 1-loop corrections [45] that we introduced in (5.34) and (5.35).

Applying the formula for every factor in the index we obtain the expression for the partition function in three dimension multiplied by a divergent prefactor, which is given by the product of the exponential factors in (5.37) for every field. It can be shown [21] that this prefactor is proportional to the $U(1)_R$ -gravity-gravity and flavour-gravity-gravity anomalies which coincide for dual theories. As a result, this factor can be removed without problems since we are considering the reduction of the index for dual theories.

The advantage of obtaining the partition functions in this way is that the equality of the partition functions for dual theories is guaranteed by the matching of the corresponding four dimensional indices. The matching of the indices for dual theories is supported by mathematical identities between integrals of elliptic gamma functions [38].

Reducing the indices to three dimensions we obtained expressions involving integrals of hyperbolic gamma functions. Mathematical identities that support the equality of the partition functions [46] are not known for every three dimensional duality. In any case, when the reduction process from four dimensions is well defined, the identity between the indices guarantees that the partition functions are identical.

Chapter 6

Dimensional reduction of $SU(N_c)$ KSS duality

The scope of this chapter is to provide an independent check of the reduction of KSS duality with $SU(N_c)$ gauge group to the Kim-Park duality [28]. We introduced these dualities in previous sections and we reviewed the procedure of dimensional reduction in field theory of [28] in section 4.3.2.

We will reduce KSS duality to three dimensions first by calculating the superconformal index in four dimensions and then reducing it to the three dimensional partition function by shrinking the radius of the circle.

As we said before, the presence of the compactified dimension induces an additional η superpotential, which can be seen in the partition function from the constraints it imposes on the real masses in the partition function. We will flow to the Kim-Park duality by assigning real masses in a similar way to section 4.3.2.

As a result, we give an alternative derivation of the reduction of KSS duality without relying on some of the assumptions made in [28].

6.1 Electric theory

The electric theory was introduced in section 2.3 and we report the charge table in order to fix our notation. For the four dimensional theory we have

	$SU(N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$
Q	N_c	N_F	1	1	$1 - R_X \frac{N_c}{N_f} = R_Q$
\tilde{Q}	$\overline{N_c}$	1	$\overline{N_F}$	-1	$1 - R_X \frac{N_c}{N_f} = R_Q$
X	$N_c^2 - 1$	1	1	0	$\frac{2}{k+1} = R_X$

(6.1)

and for the three dimensional theory

	$SU(N_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
Q	N_c	N_f	1	1	1	0	Δ_Q
\tilde{Q}	$\overline{N_c}$	1	$\overline{N_f}$	-1	1	0	Δ_Q
X	$N_c^2 - 1$	1	1	0	0	0	$\frac{2}{k+1} = \Delta_X$

(6.2)

6.1.1 Calculation of the index

The single particle index can be calculated with equations (5.10) and (5.11)

$$\begin{aligned}
i_E(p, q, v, y, \tilde{y}, z) = & \\
& - \left(\frac{p}{1-p} + \frac{q}{1-q} - \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_X}{2}} - (pq)^{1-\frac{R_X}{2}} \right) \right) (p_{N_c}(z) p_{N_c}(z^{-1}) - 1) \\
& + \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{1}{2}R_Q} v p_{N_f}(y) p_{N_c}(z) - (pq)^{1-\frac{1}{2}R_Q} \frac{1}{v} p_{N_f}(y^{-1}) p_{N_c}(z^{-1}) \right. \\
& \quad \left. + (pq)^{\frac{1}{2}R_Q} \frac{1}{v} p_{N_f}(\tilde{y}) p_{N_c}(z^{-1}) - (pq)^{1-\frac{1}{2}R_Q} v p_{N_f}(\tilde{y}^{-1}) p_{N_c}(z) \right)
\end{aligned}
\tag{6.3}$$

where p, q are defined as in the previous chapters and the other fugacities are associated to the symmetries

$$v \rightarrow U(1)_B \quad y \rightarrow SU(N_F)_L \quad \tilde{y} \rightarrow SU(N_F)_R \quad z \rightarrow SU(N_c) \tag{6.4}$$

In (6.3) we have written explicitly the character for the adjoint, fundamental and antifundamental representations of $SU(N)$, which are given by

$$\chi_{adj}(z) = p_N(z) p_N(z^{-1}) - 1 \quad \chi_N(y) = p_N(y) \quad \chi_{\bar{N}}(\tilde{y}) = p_N(\tilde{y}^{-1}) \tag{6.5}$$

$$p_N(x) = \sum_{i=1}^N x_i \quad p_N(x) = \sum_{i=1}^N \frac{1}{x_i} \tag{6.6}$$

Moreover, given that the fugacities are in the Cartan subgroup of $SU(N_c)$ or $SU(N_f)$ we have the following constraints

$$\prod_i^{N_c} z_i = 1 \quad \prod_i^{N_f} y_i = 1 \quad \prod_i^{N_f} \tilde{y}_i = 1 \tag{6.7}$$

If we use the definition of the polynomials $p_N(x)$ we obtain

$$\begin{aligned}
i_E(p, q, v, y, \tilde{y}, z) = & - \left(\frac{p}{1-p} + \frac{q}{1-q} - \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_X}{2}} - (pq)^{1-\frac{R_X}{2}} \right) \right) \left(\sum_{1 \leq i, j \leq N_c} \frac{z_i}{z_j} - 1 \right) \\
& + \frac{1}{(1-p)(1-q)} \sum_{a=1}^{N_f} \sum_{j=1}^{N_c} \left((pq)^{\frac{1}{2}R_Q} v y_a z_j - (pq)^{1-\frac{1}{2}R_Q} v^{-1} y_a^{-1} z_j^{-1} \right. \\
& \quad \left. + (pq)^{\frac{1}{2}R_Q} v^{-1} \tilde{y}_a z_j^{-1} - (pq)^{1-\frac{1}{2}R_Q} v \tilde{y}_a^{-1} z_j \right)
\end{aligned} \tag{6.8}$$

The index is given by the sum of contributions for every field in the theory

$$i_E(p, q, v, y, \tilde{y}, z) = i_E^V(p, q, z) + i_E^X(p, q, z) + i_E^{Q, \tilde{Q}}(p, q, v, y, z) \tag{6.9}$$

and the complete index is given by the Plethystic exponential

$$\begin{aligned}
I_E(p, q, v, y, \tilde{y}) &= \int_{SU(N_c)} d\mu(z) \exp \left(\sum_{n=1}^{\infty} \frac{1}{n} i_E(p^n, q^n, v^n, y^n, \tilde{y}^n, z^n) \right) \\
&= \int_{SU(N_c)} d\mu(z) \prod_{\text{fields } F} I_E^F(p, q, v, y, \tilde{y}, z)
\end{aligned} \tag{6.10}$$

where I_E^F is given by the Plethystic exponential for the field F .

Given that the fugacity z is in the maximal torus of the gauge group, we can restrict the integral to T^{N_c-1} . The integration on the gauge group reduces to

$$\int_{SU(N_c)} d\mu(z) f(z) = \frac{1}{N_c!} \int_{T^{N_c-1}} \prod_{i=1}^{N_c} \frac{dz_i}{2\pi i z_i} \Delta(z) \Delta(z^{-1}) f(z) \Big|_{\prod_{i=1}^{N_c} z_i=1} \tag{6.11}$$

where $\Delta(z)$ is the Vandermonde determinant, which is given by

$$\Delta(z) = \prod_{\substack{1 \leq i, j \leq N_c \\ i \neq j}}^{N_c} (z_i - z_j) = \prod_{\substack{1 \leq i, j \leq N_c \\ i \neq j}}^{N_c} \left(1 - \frac{z_i}{z_j} \right) z_j = \prod_{\substack{1 \leq i, j \leq N_c \\ i \neq j}}^{N_c} \left(1 - \frac{z_i}{z_j} \right)$$

where the last equality holds because $\prod_{i=1}^{N_c} z_i = 1$.

We will calculate the superconformal index by considering separately the contributions from the various fields. The complete calculations for every field can be found in appendix C.

Vector field The vector field contributes to the index as

$$\begin{aligned}
I_E^V(p, q, z) &= \exp \left(\sum_{n=1}^{\infty} \frac{1}{n} i_E^{Vett}(p^n, q^n, z^n) \right) = \\
&= \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) \left(\left(\sum_{1 \leq i, j \leq N_c} \frac{z_i^n}{z_j^n} \right) - 1 \right) \right) = \\
&= (p; p)^{N_c-1} (q; q)^{N_c-1} \prod_{1 \leq i < j \leq N_c} \frac{1}{\left(1 - \frac{z_i}{z_j}\right) \left(1 - \frac{z_j}{z_i}\right) \Gamma_e\left(\frac{z_i}{z_j}; p, q\right) \Gamma_e\left(\frac{z_j}{z_i}; p, q\right)} \\
&= (p; p)^{N_c-1} (q; q)^{N_c-1} \frac{1}{\Delta(z) \Delta(z^{-1})} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_e\left(\frac{z_i}{z_j}; p, q\right) \Gamma_e\left(\frac{z_j}{z_i}; p, q\right)}
\end{aligned} \tag{6.12}$$

Note that there is a term that cancels the Vandermonde determinant coming from the integration measure.

Adjoint matter The single particle index for this field reads

$$i_E^X(p, q, z) = \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_X}{2}} - (pq)^{1-\frac{R_X}{2}} \right) \left(\left(\sum_{1 \leq i, j \leq N_c} \frac{z_i}{z_j} \right) - 1 \right) \tag{6.13}$$

which results in

$$I_E^X(p, q, z) = \Gamma_e \left((pq)^{\frac{R_X}{2}}; p, q \right)^{N_c-1} \prod_{1 \leq i < j \leq N_c} \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_i}{z_j} \right) \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_j}{z_i} \right) \tag{6.14}$$

Quarks The quarks in the fundamental and antifundamental representation have a single particle index of the form

$$\begin{aligned}
i_E^{Q, \tilde{Q}}(p, q, v, y, \tilde{y}) &= \\
&= \frac{1}{(1-p)(1-q)} \sum_{j=1}^{N_c} \left(\sum_{a=1}^{N_f} \left((pq)^{\frac{1}{2}R_Q} v y_a z_j - (pq)^{1-\frac{1}{2}R_Q} v^{-1} y_a^{-1} z_j^{-1} \right) \right. \\
&\quad \left. + \sum_{b=1}^{N_f} \left((pq)^{\frac{1}{2}R_Q} v^{-1} \tilde{y}_b z_j^{-1} - (pq)^{1-\frac{1}{2}R_Q} v \tilde{y}_b^{-1} z_j \right) \right)
\end{aligned} \tag{6.15}$$

where Q and \tilde{Q} generate the first and second line of the index, respectively. Their contribution can be written as

$$I_E^{Q, \tilde{Q}}(p, q, v, y, \tilde{y}, z) = \prod_j^{N_c} \prod_{a,b}^{N_f} \Gamma_e \left((pq)^{\frac{R_Q}{2}} v y_a z_j \right) \Gamma_e \left((pq)^{\frac{R_Q}{2}} v^{-1} \tilde{y}_b^{-1} z_j^{-1} \right) \tag{6.16}$$

Expression of the superconformal index

The formula for the superconformal index can be obtained by multiplying all the contributions calculated above and reads

$$I_E(p, q, v, y, \tilde{y}) = \frac{(p; p)^{N_c-1} (q; q)^{N_c-1}}{N_c!} \Gamma_e \left((pq)^{\frac{R_X}{2}}; p, q \right)^{N_c-1} \\ \oint_{T^{N_c-1}} \left(\prod_{i=1}^{N_c} \frac{dz_i}{2\pi i z_i} \right) \delta \left(\prod_{i=1}^{N_c} z_i - 1 \right) \prod_{1 \leq i < j \leq N_c} \frac{\Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_i}{z_j} \right) \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_j}{z_i} \right)}{\Gamma_e \left(\frac{z_i}{z_j}; p, q \right) \Gamma_e \left(\frac{z_j}{z_i}; p, q \right)} \\ \prod_j^{N_c} \prod_{a,b}^{N_f} \Gamma_e \left((pq)^{\frac{R_Q}{2}} v y_a z_j \right) \Gamma_e \left((pq)^{\frac{R_Q}{2}} v^{-1} \tilde{y}_b^{-1} z_j^{-1} \right) \quad (6.17)$$

The index is written as an elliptic integral and as a result it is well defined only if the fugacities satisfy a balancing condition. It is given by

$$(pq)^{N_c R_X + N_f R_Q} \prod_{a=1}^{N_f} y_a y_a^{-1} = (pq)^{N_f} \quad (6.18)$$

Physically, this constraint correspond to the anomaly-free condition of the R-symmetry in four dimensions and for the compactified theory is imposed by the η superpotential.

6.1.2 Reduction of the superconformal index to the partition function

We can now proceed to reduce the index to the partition function on the squashed three sphere by applying the procedure we introduced in the previous chapter. We need to parametrize the fugacities as

$$p = e^{2\pi i r \omega_1} \quad q = e^{2\pi i r \omega_2} \quad z_i = e^{2\pi i r \sigma_i} \quad (6.19)$$

$$y_a = e^{2\pi i r m_a} \quad y_a = e^{2\pi i r \tilde{m}_a} \quad v = e^{2\pi i r m_B} \quad (6.20)$$

and we have the following conditions on the real masses

$$\sum_a m_a = 0 \quad \sum_b m_b = 0 \quad \sum_j \sigma_j = 0 \quad (6.21)$$

By using the identity (5.37) on each term we can obtain the partition function as an integral of products of hyperbolic gamma functions. An explicit calculation can be found in appendix C.2.

We will use the following notation for the hyperbolic gamma function

$$\Gamma_h(z; \omega_1, \omega_2) = \Gamma_h(z) \quad \Gamma_h(u \pm z) = \Gamma_h(u + z) \Gamma_h(u - z) \quad (6.22)$$

From now on we will denote the three dimensional R-charges of quarks as Δ_Q and as Δ_X for the adjoint matter because they are going to be different from the four dimensional values, which are fixed by the R-symmetry anomaly.

Vector field For the vector field in the adjoint representation we can use the identity (B.8) applied to $SU(N_c)$ gauge group

$$\begin{aligned} \lim_{r \rightarrow 0} \frac{(p; p)^{N_c-1} (q; q)^{N_c-1}}{N_c!} \oint_{T^{N_c-1}} \prod_{j=1}^{N_c-1} \frac{dz_j}{2\pi i z_j} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_e\left(\frac{z_i}{z_j}\right) \Gamma_e\left(\frac{z_j}{z_i}\right)} \sim \\ \sim \exp\left(-\frac{i\pi\omega(N_c^2-1)}{6r\omega_1\omega_2}\right) \frac{1}{N_c!} \int \prod_{j=1}^{N_c-1} \frac{d\sigma_j}{\sqrt{-\omega_1\omega_2}} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \end{aligned} \quad (6.23)$$

Adjoint matter

$$\begin{aligned} \Gamma_e\left((pq)^{\frac{\Delta_X}{2}}\right)^{N_c-1} \prod_{1 \leq i < j \leq N_c} \Gamma_e\left((pq)^{\frac{\Delta_X}{2}} \left(\frac{z_i}{z_j}\right)\right) \Gamma_e\left((pq)^{\frac{\Delta_X}{2}} \left(\frac{z_j}{z_i}\right)\right) \sim \\ \exp\left(-\frac{i\pi}{6r\omega_1\omega_2} \left((N_c^2-1)\omega(\Delta_X-1)\right)\right) \prod_{1 \leq i < j \leq N_c} \Gamma_h(\Delta_X\omega \pm (\sigma_i - \sigma_j)) \end{aligned} \quad (6.24)$$

Quarks

$$\begin{aligned} \prod_{a,b}^{N_f} \prod_j^{N_c} \Gamma_e\left((pq)^{\Delta_Q v y_a z_j}\right) \Gamma_e\left((pq)^{\Delta_Q v^{-1} \tilde{y}_b^{-1} z_j^{-1}}\right) = \\ = \exp\left(-\frac{i\pi}{6r\omega_1\omega_2} (2\omega N_c N_f (R_Q - 1) + N_c \sum_a m_a - N_c \sum_b \tilde{m}_b)\right) \times \\ \times \prod_{a,b}^{N_f} \prod_j^{N_c} \Gamma_h(\mu_a + \sigma_j) \Gamma_h(\nu_b - \sigma_j) \end{aligned} \quad (6.25)$$

Where we defined the real masses μ_a, ν_b

$$\mu_a = \omega \Delta_Q + m_a + m_B \quad \nu_b = \omega \Delta_Q - \tilde{m}_b - m_B \quad (6.26)$$

Divergent contribution

Summing up all the exponential terms from the previous limits we obtain

$$\exp\left[-\frac{i\pi}{6r\omega_1\omega_2} \left(\omega \left((N_c^2-1) + (N_c^2-1)(\Delta_X-1) + \right. \right. \right. \\ \left. \left. \left. + 2N_c N_f (R_Q - 1)\right) + N_c \sum_a m_a - N_c \sum_b \tilde{m}_b\right)\right] \quad (6.27)$$

which is compatible with the following general formula [21]

$$\exp\left[-\frac{i\pi\omega}{6r\omega_1\omega_2} \left(\omega \left(|G| + \sum_{\alpha} (R_{\alpha} - 1)\right) + \sum_a m_a \sum_{\alpha} e^{(\alpha)_a}\right)\right] \quad (6.28)$$

which is proportional to the gravitational anomaly [21] which is identical between the electric and the magnetic theory because of the KSS duality.

Partition function

We can write down the formula for the partition function of the electric theory by putting all these pieces together and ignoring the divergent prefactor we calculated previously. The partition function is then given by

$$Z_{el}(\mu_a, \nu_b) = \frac{1}{N_c!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{N_c-1} \int \prod_{i=1}^{N_c} \frac{d\sigma_i}{\sqrt{-\omega_1 \omega_2}} \delta(\sum_i \sigma_i) \prod_{1 \leq i < j \leq N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \prod_{a=1}^{N_f} \prod_{b=1}^{N_c} \Gamma_h(\mu_a + \sigma_j) \Gamma_h(\nu_b - \sigma_j) \quad (6.29)$$

with

$$\mu_a = \omega \Delta_Q + m_a + m_B \quad \nu_b = \omega \Delta_Q - \tilde{m}_b - m_B \quad (6.30)$$

Consider that we obtained the partition function by compactifying on S^1 we have the following condition on the real masses, obtained from (6.18)

$$\frac{1}{2} \left(\sum_a \mu_a + \nu_a \right) = \omega (-N_c + N_c(1 - \Delta_X) + N_f) \quad (6.31)$$

Note that this condition is equivalent to require that the R-symmetry in four dimension is anomaly free. As a result the R-charges of the fields for the theory with η superpotential are identical to the four dimensional R-charges, as we noted in the field theory side of the duality in the previous chapters.

6.1.3 Flow to a duality without η superpotential

In order to obtain the duality without η superpotential we start with $N_f + 1$ flavours and we assign real masses in the same way as (4.46).

The real mass assignment breaks the gauge group $SU(N_f + 1)_L \times SU(N_f + 1)_R \times U(1)_B \rightarrow SU(N_f)_L \times SU(N_f)_R \times U(1)_A \times U(1)_B$.

We will assign a large value to the mass m . The real masses are given by

$$\begin{aligned} \mu_a &= \begin{cases} \omega \Delta_Q + m_a + m_A + m_B & a = 1, \dots, N_f \\ \omega \Delta_M + m - m_A N_f + m_B & a = N_f + 1 \end{cases} \\ \nu_b &= \begin{cases} \omega \Delta_Q + \tilde{m}_b + m_A - m_B & b = 1, \dots, N_f \\ \omega \Delta_M - m - m_A N_f - m_B & b = N_f + 1 \end{cases} \end{aligned} \quad (6.32)$$

The R-charge of the last flavour is different from the other quarks because the axial symmetry $U(1)_A$ mixes with the R-symmetry.

With this real mass assignment we can now perform the limit $m \rightarrow \infty$ which can be done on the partition function using the following mathematical identity for the hyperbolic gamma function [46]

$$\lim_{t \rightarrow \infty} \Gamma_h(z + t; \omega_1, \omega_2) = \exp \left[\text{sign}(t) \frac{\pi i}{2\omega_1 \omega_2} \left((z + t - \omega)^2 - \frac{\omega_1^2 + \omega_2^2}{12} \right) \right] \quad (6.33)$$

Applying this identity to the terms associated to the last flavour of quarks that have mass m we obtain

$$\begin{aligned}\Gamma_h(\mu_{N_f+1}(m) + \sigma_i) &= \exp \left(\text{sign}(m) \frac{\pi i}{2\omega_1\omega_2} \left[[\omega(\Delta_M - 1) + \sigma_i + \right. \right. \\ &\quad \left. \left. + (m + m_B - N_f m_A)]^2 - \frac{\omega_1^2 + \omega_2^2}{12} \right] \right) \\ \Gamma_h(\nu_{N_f+1}(m) - \sigma_i) &= \exp \left(\text{sign}(-m) \frac{\pi i}{2\omega_1\omega_2} \left[[\omega(\Delta_M - 1) - \sigma_i + \right. \right. \\ &\quad \left. \left. (-m - m_B - N_f m_A)]^2 - \frac{\omega_1^2 + \omega_2^2}{12} \right] \right)\end{aligned}\tag{6.34}$$

Inserting these expressions in the partition function we obtain

$$\begin{aligned}&\prod_{i=1}^{N_c} \exp \left[\frac{\pi i}{2\omega_1\omega_2} \left[4(m + m_B)(\omega(\Delta_M - 1) - m_A N_f) + 4\sigma_i(\omega(\Delta_M - 1) - m_A N_f) \right] \right] = \\ &\exp \left[\frac{\pi i}{2\omega_1\omega_2} \left[4N_c(m + m_B)(\omega(\Delta_M - 1) - m_A N_f) + 4 \left(\sum_{i=1}^{N_c} \sigma_i \right) (\omega(\Delta_M - 1) - m_A N_f) \right] \right]\end{aligned}\tag{6.35}$$

We can define the $c(x) = e^{\frac{i\pi x}{2\omega_1\omega_2}}$ in order to ease the notation. The exponential factor then becomes

$$c(4N_c(m + m_B)(\omega(\Delta_M - 1) - m_A N_f)) c\left(4 \left(\sum_{i=1}^{N_c} \sigma_i \right) (\omega(\Delta_M - 1) - m_A N_f)\right)\tag{6.36}$$

We can now use the condition on the real masses that is generated by the η superpotential (6.31) which reads

$$\frac{1}{2} \sum_a \mu_a + \nu_a = \omega(-N_c \Delta_X + N_f + 1) = \omega(N_f \Delta_Q + \Delta_M)\tag{6.37}$$

Using this condition we can write the R-charge of last flavour Δ_M as a function of the real masses of the light quarks and the exponential factor reads

$$\begin{aligned}&c(4N_c(m + m_B)(\omega(N_f(1 - \Delta_Q) - N_c \Delta_X) - m_A N_f)) \\ &\quad c\left(4 \left(\sum_{i=1}^{N_c} \sigma_i \right) (\omega(N_f(1 - \Delta_Q) - N_c \Delta_X) - m_A N_f)\right)\end{aligned}\tag{6.38}$$

The terms on the first line can be taken outside the integral and we will found an identical term in the magnetic theory. The second term will be set to one by the delta function $\delta(\sum_i \sigma_i)$ upon integration.

The partition function for the electric theory after integrating out the $N_f + 1$ -th

flavour is then given by

$$\begin{aligned}
Z_{el}(\mu_i, \nu_i) = & c(4N_c(m + m_B)(-m_A N_f + \omega(N_f(1 - \Delta) - N_c \Delta_X))) \frac{1}{N_c!} \Gamma_h(\Delta_X \omega)^{N_c-1} \\
& \int \prod_{i=1}^{N_c} \frac{d\sigma_i}{\sqrt{-\omega_1 \omega_2}} \delta(\sum_i \sigma_i) \prod_{1 \leq i < j \leq N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \\
& \prod_{a,b=1}^{N_f} \prod_{j=1}^{N_c} \Gamma_h(m_a + m_B + m_A + \sigma_j) \Gamma_h(-\tilde{m}_a - m_B + m_A - \sigma_j) \quad (6.39)
\end{aligned}$$

Note that except for the exponential factors discussed above, it corresponds to the partition function for a pure three-dimensional theory, without η superpotential. The charges can be easily read off from the partition function and are given by

Fields	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
Q	N_f	0	N_c	1	0	Δ_Q
\tilde{Q}	0	$\overline{N_f}$	$-N_c$	1	0	Δ_Q
X	0	0	0	0	0	Δ_X

6.2 Magnetic theory

The four dimensional theory of Kutasov-Schwimmer duality was introduced in section 2.3. It is a $SU(\tilde{N}_c) = SU(kN_f - N_c)$ SQCD theory with N_f flavours q, \tilde{q} , a matter field Y in the adjoint representation and k mesons M_j that are identified with the electric mesons. There is a superpotential for the adjoint field $\text{Tr } Y^{k+1}$ that results in the condition $R_X = R_Y$. The four dimensional magnetic theory can be summarized by

	$SU(\tilde{N}_c)$	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_R$	
q	\tilde{N}_c	$\overline{N_f}$	1	$\frac{N_c}{kN_f - N_c}$	$1 - \frac{2}{k+1} \frac{\tilde{N}_c}{N_f} = R_q$	(6.40)
\tilde{q}	\tilde{N}_c	1	N_f	$-\frac{N_c}{kN_f - N_c}$	$1 - \frac{2}{k+1} \frac{\tilde{N}_c}{N_f} = R_q$	
Y	1	$\tilde{N}_c^2 - 1$	1	0	$\frac{2}{k+1} = R_X$	
M_j	1	N_f	$\overline{N_f}$	0	$2 - \frac{4}{k+1} \frac{N_c}{N_f} + j \frac{2}{k+1}$	

and the three dimensional one by

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$	
q	N_f	1	$\frac{N_c}{kN_f - N_c}$	1	0	Δ_Q	(6.41)
\tilde{q}	1	$\overline{N_f}$	$-\frac{N_c}{kN_f - N_c}$	1	0	Δ_Q	
Y	1	1	0	0	0	$\frac{2}{k+1} = \Delta_Y$	
M_j	N_f	$\overline{N_f}$	0	2	0	$2\Delta_Q + j \frac{2}{k+1}$	

6.2.1 Superconformal index

We will now repeat the process that was applied to the electric theory for the magnetic side. The single particle index is given by

$$\begin{aligned}
i_M(p, q, \tilde{v}, y, \tilde{y}, \tilde{z}) = & \\
& - \left(\frac{p}{1-p} + \frac{q}{1-q} - \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_Y}{2}} - (pq)^{1-\frac{R_Y}{2}} \right) \right) (p_{\tilde{N}_c}(\tilde{z}) p_{\tilde{N}_c}(\tilde{z}^{-1}) - 1) + \\
& + \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{1}{2}R_q} \tilde{v} p_{N_f}(y^{-1}) p_{\tilde{N}_c}(\tilde{z}) - (pq)^{1-\frac{1}{2}R_q} \frac{1}{\tilde{v}} p_{N_f}(y) p_{\tilde{N}_c}(\tilde{z}^{-1}) + \right. \\
& \quad \left. + (pq)^{\frac{1}{2}R_q} \frac{1}{\tilde{v}} p_{N_f}(\tilde{y}) p_{\tilde{N}_c}(\tilde{z}^{-1}) - (pq)^{1-\frac{1}{2}R_q} \tilde{v} p_{N_f}(\tilde{y}^{-1}) p_{\tilde{N}_c}(\tilde{z}) \right) + \\
& \quad \sum_{l=0}^{k-1} \left((pq)^{R_Q+l\frac{R_Y}{2}} p_{N_f}(y) p_{N_f}(\tilde{y}^{-1}) - (pq)^{1-(R_Q+l\frac{R_Y}{2})} p_{N_f}(y^{-1}) p_{N_f}(\tilde{y}) \right)
\end{aligned} \tag{6.42}$$

where R_q is the R-charge of the dual quark which is fixed in term of the charge R_Q of the electric quark by requiring the validity of the duality. The last line is the contribution from the k different mesons.

Using the explicit form of the polynomials $p_N(x)$ we have

$$\begin{aligned}
i_M(p, q, \tilde{v}, y, \tilde{y}, \tilde{z}) = & \\
& - \left(\frac{p}{1-p} + \frac{q}{1-q} - \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_Y}{2}} - (pq)^{1-\frac{R_Y}{2}} \right) \right) \left(\sum_{i,j}^{\tilde{N}_c} \tilde{z}_i \tilde{z}_j^{-1} - 1 \right) + \\
& + \frac{1}{(1-p)(1-q)} \left[\sum_j^{\tilde{N}_c} \left(\sum_a^{N_f} \left((pq)^{\frac{1}{2}R_q} \tilde{v} y_a^{-1} \tilde{z}_j \right) - (pq)^{1-\frac{1}{2}R_q} \frac{1}{\tilde{v}} y_a \tilde{z}_j^{-1} + \right. \right. \\
& \quad \left. \left. + \sum_b^{N_f} \left((pq)^{\frac{1}{2}R_q} \frac{1}{\tilde{v}} (\tilde{y}_b) (\tilde{z}_j^{-1}) - (pq)^{1-\frac{1}{2}R_q} \tilde{v} \tilde{y}_b^{-1} \tilde{z}_j \right) \right) + \right. \\
& \quad \left. \sum_a^{N_f} \sum_b^{N_f} \sum_{l=0}^{k-1} \left((pq)^{R_Q+l\frac{R_Y}{2}} y_a \tilde{y}_b^{-1} - (pq)^{1-(R_Q+l\frac{R_Y}{2})} y_a^{-1} \tilde{y}_b \right) \right]
\end{aligned} \tag{6.43}$$

The index is now formally similar to the electric one except for the contribution of the mesons which can be calculated by identifying the $(pq)^{R_Q+l\frac{R_Y}{2}} y_a \tilde{y}_b^{-1}$ with the argument of the elliptic gamma function. Their contribution reads

$$\exp \left(\sum_n \frac{1}{n} i_M^{Meson}(p^n, q^n, \tilde{v}^n, y^n, \tilde{y}^n) \right) = \prod_a^{N_f} \prod_b^{N_f} \prod_{l=0}^{k-1} \Gamma_e((pq)^{R_Q+l\frac{R_Y}{2}} y_a \tilde{y}_b^{-1}; p, q) \tag{6.44}$$

The complete expression for the superconformal index for the magnetic theory is given by

$$\begin{aligned}
I_{Mag}(p, q, y, \tilde{v}, \tilde{y}) = & \frac{1}{\tilde{N}_c!} (p; p)^{\tilde{N}_c-1} (q; q)^{\tilde{N}_c-1} \Gamma_e((pq)^{\frac{R_Y}{2}}; p, q)^{\tilde{N}_c-1} \left(\prod_a^{N_f} \prod_b^{N_f} \prod_{l=0}^{k-1} \Gamma_e((pq)^{R_Q+l\frac{R_Y}{2}} y_a \tilde{y}_b^{-1}; p, q) \right) \\
& \int \left(\prod_{i=1}^{\tilde{N}_c} \frac{dz_i}{2\pi i z_i} \right) \delta \left(\prod_{i=1}^{\tilde{N}_c} z_i - 1 \right) \prod_{1 \leq i < j \leq \tilde{N}_c} \frac{\Gamma_e((pq)^{\frac{R_Y}{2}} \frac{z_i}{z_j}) \Gamma_e((pq)^{\frac{R_Y}{2}} \frac{z_j}{z_i})}{\Gamma_e(\frac{z_i}{z_j}; p, q) \Gamma_e(\frac{z_j}{z_i}; p, q)} \\
& \prod_j^{\tilde{N}_c} \prod_{a,b}^{N_f} \Gamma_e((pq)^{\frac{1}{2}R_q} \tilde{v} y_a^{-1} \tilde{z}_j; p, q) \Gamma_e((pq)^{\frac{1}{2}R_q} \tilde{v}^{-1} \tilde{y}_b \tilde{z}_j^{-1}; p, q) \quad (6.45)
\end{aligned}$$

6.2.2 Reduction to the partition function

We reduce the index to the partition function using the same procedure employed for the electric theory.

Vector field We can use the identity (B.8) as in the electric theory with \tilde{N}_c and $\tilde{\sigma}$ instead of N_c and σ . The result is

$$\begin{aligned}
& \lim_{r \rightarrow 0} \frac{(p; p)^{\tilde{N}_c-1} (q; q)^{\tilde{N}_c-1}}{\tilde{N}_c!} \oint_{T^{\tilde{N}_c-1}} \prod_{j=1}^{\tilde{N}_c-1} \frac{d\tilde{z}_j}{2\pi i \tilde{z}_j} \prod_{1 \leq i < j \leq \tilde{N}_c} \frac{1}{\Gamma_e(\frac{\tilde{z}_i}{\tilde{z}_j}) \Gamma_e(\frac{\tilde{z}_j}{\tilde{z}_i})} \sim \\
& \sim \exp \left(-\frac{i\pi\omega(\tilde{N}_c^2 - 1)}{6r\omega_1\omega_2} \right) \frac{1}{\tilde{N}_c!} \int \prod_{j=1}^{\tilde{N}_c-1} \frac{d\tilde{\sigma}_j}{\sqrt{-\omega_1\omega_2}} \prod_{1 \leq i < j \leq \tilde{N}_c} \frac{1}{\Gamma_h(\pm(\tilde{\sigma}_i - \tilde{\sigma}_j))} \quad (6.46)
\end{aligned}$$

Adjoint matter The reduction of the adjoint matter is identical to the electric theory (using (5.37)) which results in

$$\begin{aligned}
& \Gamma_e \left((pq)^{\frac{\Delta_Y}{2}} \right)^{\tilde{N}_c-1} \prod_{1 \leq i < j \leq \tilde{N}_c} \Gamma_e \left((pq)^{\frac{\Delta_Y}{2}} \left(\frac{\tilde{z}_i}{\tilde{z}_j} \right) \right) \Gamma_e \left((pq)^{\frac{\Delta_Y}{2}} \left(\frac{\tilde{z}_j}{\tilde{z}_i} \right) \right) \sim \\
& \exp \left(-\frac{i\pi}{6r\omega_1\omega_2} \left((\tilde{N}_c^2 - 1)\omega(\Delta_Y - 1) \right) \right) \prod_{1 \leq i < j \leq \tilde{N}_c} \Gamma_h(\Delta_Y\omega \pm (\tilde{\sigma}_i - \tilde{\sigma}_j)) \quad (6.47)
\end{aligned}$$

Quarks

$$\begin{aligned}
& \prod_j^{\tilde{N}_c} \prod_{a,b}^{N_f} \Gamma_e((pq)^{\frac{1}{2}\Delta_q} \tilde{v} y_i^{-1} \tilde{z}_j; p, q) \Gamma_e((pq)^{\frac{1}{2}\Delta_q} \tilde{v}^{-1} \tilde{y}_b \tilde{z}_j^{-1}; p, q) = \\
& = \exp \left(\frac{-i\pi}{6r\omega_1\omega_2} \left(2N_f \tilde{N}_c \omega(\Delta_q - 1) + \tilde{N}_c \left(\sum_{a=1}^{N_f} -m_a + \tilde{m}_a \right) \right) \right) \Gamma_h(\tilde{\mu}_a + \tilde{\sigma}_j) \Gamma_h(\tilde{\nu}_b - \tilde{\sigma}_j) \quad (6.48)
\end{aligned}$$

where we defined the real masses $\tilde{\mu}_a, \tilde{\nu}_b$

$$\tilde{\mu}_a = -m_a + \tilde{m}_B + \omega \Delta_q \quad \tilde{\nu}_b = +\tilde{m}_b - \tilde{m}_B + \omega \Delta_q \quad (6.49)$$

Note that the signs for the masses associated to the flavour group are inverted with respect to the electric theory (6.32), because the quarks are in opposite representations. Moreover, we denoted \tilde{m}_B as the baryonic mass in the magnetic theory. It can be related to the electric baryonic mass by

$$\tilde{m}_B = \frac{N_c}{kN_f - N_c} m_B \quad (6.50)$$

In addition, the R-charges of the dual quarks are fixed by the superpotential interaction with the mesons which results in the condition

$$R_q = R_Y - R_Q \quad \xrightarrow{3D} \quad \Delta_q = \Delta_Y - \Delta_Q \quad (6.51)$$

The real masses are then

$$\tilde{\mu}_a = -m_a + \frac{N_c}{kN_f - N_c} m_B + \omega(\Delta_X - \Delta_Q) \quad \tilde{\nu}_b = +\tilde{m}_b - \frac{N_c}{kN_f - N_c} m_B + \omega(\Delta_X - \Delta_Q) \quad (6.52)$$

Mesons Applying the same procedure to the mesons we obtain

$$\begin{aligned} & \prod_a^{N_f} \prod_b^{N_f} \prod_{l=0}^{k-1} \Gamma_e((pq)^{\frac{1}{2}(2\Delta_Q + l\Delta_X)} y_a \tilde{y}_b^{-1}; p, q) = \\ & \exp \left(\frac{-i\pi}{6r\omega_1\omega_2} \left(\omega N_f^2 \sum_{l=0}^{k-1} \left(2 \left(\Delta_Q - \frac{1}{2} \right) + l\Delta_X \right) + N_f \left(\sum_{l=0}^{k-1} \sum_i^{N_f} m_i - \tilde{m}_i \right) \right) \right) \\ & \prod_a^{N_f} \prod_b^{N_f} \prod_{l=0}^{k-1} \Gamma_h(\omega(2\Delta_Q + l\Delta_X) + m_a - \tilde{m}_b) \quad (6.53) \end{aligned}$$

Divergent contributions

Summing up all the contributions from the various fields we obtain the following expression

$$\begin{aligned} & \omega(\tilde{N}_c^2 - 1) + \left(\omega N_f^2 \sum_{l=0}^{k-1} \left(2 \left(\Delta_Q - \frac{1}{2} \right) + l\Delta_X \right) + N_f \left(\sum_{l=0}^{k-1} \sum_i^{N_f} m_i - \tilde{m}_i \right) \right) + \\ & + \left((\tilde{N}_c^2 - 1)\omega(\Delta_Y - 1) \right) + \left(2N_f \tilde{N}_c \omega(\Delta_q - 1) + \tilde{N}_c \sum_{a=1}^{N_f} -m_a + \tilde{m}_a \right) \quad (6.54) \end{aligned}$$

We can verify that it is identical to the divergent contribution that we obtained in the electric theory by using the explicit value of $\tilde{N}_c = kN_f - N_c$, $\Delta_Y = \Delta_X = \frac{2}{k+1}$

and $\Delta_q = \Delta_X - \Delta_Q$. Note that this matching is a non trivial check of the duality and it corresponds to the 't Hooft anomaly matching for the gravitational anomalies. The complete calculation can be found in appendix D. The final expression is identical to the electric one and is given by

$$\omega(N_c^2 - 1) + (N_c^2 - 1)\omega(\Delta_X - 1) + 2N_f N_c \omega(\Delta_Q - 1) + N_c \left(\sum_a^{N_f} m_a - \tilde{m}_a \right) \quad (6.55)$$

6.2.3 Partition function

The partition function for the magnetic theory without the divergent factor is given by

$$\begin{aligned} Z_{mag}(\mu_a, \nu_b, \tilde{\mu}_a, \tilde{\nu}_b) = & \frac{1}{\tilde{N}_c!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{\tilde{N}_c - 1} \left(\prod_{a,b=1}^{N_f} \prod_{l=0}^{k-1} \Gamma_h(\mu_a + \nu_b + l\omega\Delta_X) \right) \\ & \int \prod_{i=1}^{kN_f - N_c} d\tilde{\sigma}_i \delta\left(\sum_i \tilde{\sigma}_i\right) \prod_{i < j}^{kN_f - N_c} \frac{\Gamma_h(\Delta_Y \omega \pm (\tilde{\sigma}_i - \tilde{\sigma}_j))}{\Gamma_h(\pm(\tilde{\sigma}_i - \tilde{\sigma}_j))} \\ & \prod_{a,b=1}^{N_f} \prod_{j=1}^{kN_f - N_c} \Gamma_h(\tilde{\mu}_a + \tilde{\sigma}_j) \Gamma_h(\tilde{\nu}_b - \tilde{\sigma}_j) \end{aligned} \quad (6.56)$$

where we defined

$$\begin{aligned} \mu_a &= \omega\Delta_Q + m_a & \nu_a &= \omega\Delta_Q - \tilde{m}_a \\ \tilde{\mu}_a &= \omega(\Delta_X - \Delta_Q) + \frac{N_c}{kN_f - N_c} m_B - m_a & \tilde{\nu}_a &= \omega(\Delta_X - \Delta_Q) - \frac{N_c}{kN_f - N_c} m_B + \tilde{m}_a \end{aligned} \quad (6.57)$$

where the same condition (6.31) on the R-charges and real masses holds.

6.2.4 Flow to a theory without η superpotential

We need to perform the same procedure we already applied to the electric theory in order to flow to a pure three dimensional theory.

We start from a $SU(k(N_f + 1) - N_c)$ gauge theory with $N_f + 1$ flavours, adjoint matter and $k(N_f + 1)^2$ mesons singlets. We break the global symmetry group in the same way as we did in the electric side.

Considering that we have already chosen a vacuum on the electric side, we need to find the vacuum on the magnetic side that can be matched with the electric one.

The mapping of the real masses, considering the divergent terms is the following

$$\begin{aligned}\tilde{\mu}_a &= \begin{cases} \tilde{\mu}_a = \omega(\Delta_X - \Delta_Q) + m_B \frac{N_c}{k(N_f+1) - N_c} - m_a - m_A + m_1 & a = 1 \dots N_f \\ \tilde{\mu}_{N_f+1} = \omega(\Delta_X - \Delta_M) + m_B \frac{N_c}{k(N_f+1) - N_c} + m_A N_f + m_2 \end{cases} \\ \tilde{\nu}_a &= \begin{cases} \tilde{\nu}_b = \omega(\Delta_X - \Delta_Q) - m_B \frac{N_c}{k(N_f+1) - N_c} + \tilde{m}_b - m_A - m_1 & a = 1 \dots N_f \\ \tilde{\nu}_{N_f+1} = \omega(\Delta_X - \Delta_M) - m_B \frac{N_c}{k(N_f+1) - N_c} + m_A N_f - m_2 \end{cases}\end{aligned}\quad (6.58)$$

where we set

$$m_1 = \frac{k}{k(N_f+1) - N_c} m \quad m_2 = \frac{N_c - kN_f}{k(N_f+1) - N_c} m \quad (6.59)$$

The masses for the mesons are different, because they are not charged under the baryonic symmetry and the mass m in the electric theory is the result of the sum of flavour and baryonic divergent mass terms. As a result they are given by

$$\begin{aligned}\mu_a &= \begin{cases} m_a + m_A - M + \omega\Delta \\ MN_f - m_A N_f + \omega\Delta_M \end{cases} \\ \nu_a &= \begin{cases} -\tilde{m}_a + m_A + M + \omega\Delta \\ -MN_f - m_A N_f + \omega\Delta_M \end{cases}\end{aligned} \quad \text{with } M = \frac{m}{N_f+1} \quad (6.60)$$

The mapping of real masses between electric and magnetic theory is identical to the one discussed in section 4.3.2. As in section 4.3.2 we need to find the vacuum for $\tilde{\sigma}$ such that we have the most number of massless degrees of freedom. However, considering that we don't have to introduce the polynomial deformation in the adjoint matter, the vacuum will be different. It is given by

$$\tilde{\sigma}_{VEV} = \begin{pmatrix} -m_1 \mathbf{1}_{kN_f - N_c} & 0 \\ 0 & -m_2 \mathbf{1}_k \end{pmatrix} \quad (6.61)$$

Note that this vacuum choice is traceless.

This vacuum expectation value for σ is more symmetric than (4.57) and breaks the gauge group only as $U(kN_f - N_c) \times U(k)/U(1)$. From now on, with $\tilde{\sigma}$ we will refer first $kN_f - N_c$ entries and with ρ with the other k entries of the original gauge scalar.

We can now perform the limit $m \rightarrow \infty$ on the partition by using the identity (6.33).

Mesons Most of the components of the mesons remains massless, because only the non diagonal $M_i^{N_f+1}$ and $M_{N_f+1}^i$ terms are massive.

$$\begin{aligned}
& \prod_a^{N_f+1} \prod_b^{N_f+1} \prod_{l=0}^{k-1} \Gamma_h(\mu_a + \nu_b + l\omega\Delta_X) = \\
& \left(\prod_{l=0}^{k-1} \left(\prod_a^{N_f} \prod_b^{N_f} \Gamma_h(\mu_a + \nu_b + l\omega\Delta_X) \right) \right) \Gamma_h(-2m_A N_f + \omega(2\Delta_M + l\Delta_X)) \\
& \left(\prod_{l=0}^{k-1} \prod_a^{N_f} \Gamma_h(m_a - m_A(N_f - 1) - \underbrace{M(N_f + 1)}_m + \omega(\Delta_Q + \Delta_M + l\Delta_X)) \right. \\
& \left. \Gamma_h(-\tilde{m}_a + \underbrace{M(N_f + 1)}_m - m_A(N_f - 1) + \omega(\Delta_Q + \Delta_M + l\Delta_X)) \right)
\end{aligned} \tag{6.62}$$

Using the identity for the terms in the last two rows we obtain an exponential factor given by

$$\exp \left\{ \frac{\pi i}{2\omega_1\omega_2} \sum_{l=0}^{k-1} \sum_a^{N_f} \left[-m_a^2 + \tilde{m}_a^2 + 4m(m_A(N_f - 1) + \omega(\Delta_Q + \Delta_M + l\Delta_X - 1)) \right] \right\} \tag{6.63}$$

Quarks The vacuum expectation value for $\tilde{\sigma}$ was chosen such that only the off-diagonal components would become massive, similarly to the mesons.

$$\begin{aligned}
& \left(\prod_{i=1}^{N_f} \prod_{j=1}^{kN_f-N_c} \Gamma_h(\tilde{\mu}_i + \tilde{\sigma}_j) \Gamma_h(\tilde{\nu}_i - \tilde{\sigma}_j) \right) \left(\prod_{j=1}^k \Gamma_h(\tilde{\mu}_{N_f+1} + \rho_j) \Gamma_h(\tilde{\nu}_{N_f+1} - \rho_j) \right) \\
& \left(\prod_{j=1}^{kN_f-N_c} \Gamma_h(\tilde{\mu}_{N_f+1} + \tilde{\sigma}_j) \Gamma_h(\tilde{\nu}_{N_f+1} - \tilde{\sigma}_j) \right) \left(\prod_{i=1}^{N_f} \prod_{j=1}^k \Gamma_h(\tilde{\mu}_i + \rho_j) \Gamma_h(\tilde{\nu}_i - \rho_j) \right)
\end{aligned} \tag{6.64}$$

The terms from the first line corresponds to massless quarks, while the second contains massless components that will generate exponential terms.

The result of the limit $m \rightarrow \infty$ on the first of these terms gives

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \prod_{j=1}^{kN_f-N_c} \Gamma_h(\tilde{\mu}_{N_f+1} + \tilde{\sigma}_j) \Gamma_h(\tilde{\nu}_{N_f+1} - \tilde{\sigma}_j) = \\
& \exp \left\{ \frac{i\pi}{2\omega_1\omega_2} \left[\left(\sum_j^{kN_f-N_c} 4\sigma'_j (-m_A N_f - \omega(\Delta_X - \Delta_M - 1)) \right) + \right. \right. \\
& \left. \left. 4(kN_f - N_c) \left(m_B \frac{N_c}{k(N_f + 1) - N_c} (-m_A N_f - \omega(\Delta_X - \Delta_M - 1)) + \right. \right. \right. \\
& \left. \left. \left. m(m_A N_f + \omega(\Delta_X - \Delta_M - 1)) \right) \right] \right\} \tag{6.65}
\end{aligned}$$

While the other term gives

$$\begin{aligned} & \left(\prod_{i=1}^{N_f} \prod_{j=1}^k \Gamma_h(\tilde{\mu}_i + \rho_j) \Gamma_h(\tilde{\nu}_i - \rho_j) \right) = \\ & \exp \left\{ \left[\frac{i\pi}{2\omega_1\omega_2} \left(4N_f \sum_{j=1}^k \rho'_j (-m_A + \omega(\Delta_X - \Delta_Q - 1)) \right) \right. \right. \\ & + k \sum_a^{N_f} (m_a^2 - \tilde{m}_a^2) + 4kN_f \left(m_B \frac{N_c}{k(N_f + 1) - N_c} (-m_A + \omega(\Delta_X - \Delta_Q - 1)) \right. \\ & \left. \left. \left. + m(-m_A + \omega(\Delta_X - \Delta_Q - 1)) \right) \right] \right\} \quad (6.66) \end{aligned}$$

Adjoint matter The term associated to the adjoint matter can be written as

$$\begin{aligned} & \prod_{i < j}^{k(N_f+1)-N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\tilde{\sigma}_i - \tilde{\sigma}_j))}{\Gamma_h(\pm(\tilde{\sigma}_i - \tilde{\sigma}_j))} = \prod_{i < j}^{kN_f-N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\tilde{\sigma}_i - \tilde{\sigma}_j))}{\Gamma_h(\pm(\tilde{\sigma}_i - \tilde{\sigma}_j))} \\ & \prod_{i < j}^k \frac{\Gamma_h(\Delta_X \omega \pm (\rho_i - \rho_j))}{\Gamma_h(\pm(\rho_i - \rho_j))} \prod_{i \leq kN_f-N_c} \prod_{j \leq k} \frac{\Gamma_h(\Delta_X \omega \pm (\tilde{\sigma}_i - \rho_j))}{\Gamma_h(\pm(\tilde{\sigma}_i - \rho_j))} \quad (6.67) \end{aligned}$$

where only the last term represent massive contributions. The exponential term associated to this factor is

$$\exp \left\{ \frac{i\pi}{2\omega_1\omega_2} \left[4\omega\Delta_X \left(k(kN_f - N_c)(m) + \sum_{i=1}^{kN_f-N_c} \sum_{j=1}^k (\sigma'_i + \rho'_j) \right) \right] \right\} \quad (6.68)$$

Summation of the contribution We expect that the sum of the contributions from the various term will be similar to the divergent factors we found in the electric theory in order to the remaining partition functions to be equal. By an explicit calculation we can see that this is indeed true (appendix D). In fact, we have

$$\begin{aligned} & \exp \left\{ \frac{i\pi}{2\omega_1\omega_2} \left(4 \left(N_c(m + m_B) + \left(\sum_{i=1}^{kN_f-N_c} \tilde{\sigma}_i \right) + \left(\sum_{j=1}^k \rho_j \right) \right) \right. \right. \\ & \left. \left. \left(-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q)) \right) \right) \right\} \quad (6.69) \end{aligned}$$

The term proportional to $m + m_B$ are identical to what we found in the electric theory while we will analyze the other two terms once we have write down the partition function.

Partition function

The partition function is given by multiplying the terms we found in the previous sections. We wrote down explicitly the δ -function as $e^{2\pi i \xi \sum_i \sigma_i}$. This is equivalent to the gauging of the topological symmetry $U(1)_J$, because a term like this is generated by a Fayet-Iliopoulos term, which corresponds to the charge of the topological symmetry. This term will be crucial in the following considerations on the partition function.

$$\begin{aligned}
Z_{mag} = & \frac{1}{(kN_f - N_c)! k!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{(k(N_f+1)-N_c)-1} \\
& c(4N_c(m_B + m)(-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q)))) \\
& \left(\prod_{j=0}^{k-1} \left(\prod_{a=1}^{N_f} \prod_{b=1}^{N_f} \Gamma_h(\mu_a + \nu_b + j\omega \Delta_X) \right) \Gamma_h(-2m_A N_f + \omega(2\Delta_M + j\Delta_X)) \right) \\
& \int \prod_{i=1}^{kN_f - N_c} \frac{d\sigma_i}{\sqrt{-\omega_1 \omega_2}} \prod_{i=1}^k \frac{d\rho_i}{\sqrt{-\omega_1 \omega_2}} \int d\xi e^{2\pi i \xi (\sum \sigma_i + \sum \rho_i)} \\
& \prod_{i < j}^{kN_f - N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \prod_{i < j}^k \frac{\Gamma_h(\Delta_X \omega \pm (\rho_i - \rho_j))}{\Gamma_h(\pm(\rho_i - \rho_j))} \\
& \left(\prod_{a,b=1}^{N_f} \prod_{j=1}^{kN_f - N_c} \Gamma_h \left(\left(\tilde{\sigma}_j + m_B \frac{N_c}{k(N_f + 1) - N_c} \right) - m_a - m_A + \omega(\Delta_X - \Delta_Q) \right) \right. \\
& \quad \left. \Gamma_h \left(- \left(\tilde{\sigma}_j + m_B \frac{N_c}{k(N_f + 1) - N_c} \right) + \tilde{m}_b - m_A + \omega(\Delta_X - \Delta_Q) \right) \right) \\
& \left(\prod_{i=1}^k \Gamma_h \left(\pm(\rho_i + m_B \frac{N_c}{k(N_f + 1) - N_c}) + m_A N_f + \omega(\Delta_X - \Delta_M) \right) \right) \\
& c \left(4 \left(\sum_{i=1}^{kN_f - N_c} \sigma_i + \sum_{j=1}^k \rho_j \right) (-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q))) \right)
\end{aligned} \tag{6.70}$$

We need to rescale ξ in order to normalize its contribution to the partition function as a standard Fayet-Iliopoulos term. This is achieved by the following rescaling

$$\xi \longrightarrow \frac{\xi}{\omega_1 \omega_2} \quad d\xi \longrightarrow |\omega_1 \omega_2| d\xi \tag{6.71}$$

We can remove the term, proportional to $\sum_i \tilde{\sigma}_i + \sum_j \rho_j$ in the last line by a finite shift in ξ .

With a shift in σ_i and ρ_j we can renormalize the baryonic charges such that the baryonic real mass appear with a prefactor of $\frac{N_c}{kN_f - N_c}$, which is the standard

charge associated to N_f flavours. The (traceless) shift is given by

$$\begin{aligned}\sigma_i &\longrightarrow \sigma_i + \frac{kN_c}{(kN_f - N_c)(k(N_f + 1) - N_c)} m_B \\ \rho_j &\longrightarrow \rho_j - \frac{N_c}{(k(N_f + 1) - N_c)} m_B\end{aligned}\tag{6.72}$$

Moreover, this shift makes the $U(k)$ quarks uncharged under the baryonic symmetry. The gamma function associated to them is not function of the baryonic mass anymore.

After these consideration the partition function can be rewritten as

$$\begin{aligned}Z_{mag} = & \frac{1}{(kN_f - N_c)! k!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{(k(N_f+1)-N_c)-1} \\ & \left(\prod_{j=0}^{k-1} \left(\prod_{a=1}^{N_f} \prod_{b=1}^{N_f} \Gamma_h(\mu_a + \nu_b + j\omega \Delta_X) \right) \Gamma_h(-2m_A N_f + 2\omega(\Delta_M + j\Delta_X)) \right) \\ & \int \prod_{i=1}^{kN_f - N_c} \frac{d\sigma_i}{\sqrt{-\omega_1 \omega_2}} \prod_{i=1}^k \frac{d\rho_i}{\sqrt{-\omega_1 \omega_2}} \int |\omega_1 \omega_2| d\xi e^{\frac{2\pi i \xi}{\omega_1 \omega_2} (\sum \sigma_i + \sum \rho_i)} \\ & \prod_{i < j}^{kN_f - N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \prod_{i < j}^k \frac{\Gamma_h(\Delta_X \omega \pm (\rho_i - \rho_j))}{\Gamma_h(\pm(\rho_i - \rho_j))} \\ & \left(\prod_{a,b=1}^{N_f} \prod_{j=1}^{kN_f - N_c} \Gamma_h \left(\left(\tilde{\sigma}_j + m_B \frac{N_c}{kN_f - N_c} \right) - m_a - m_A + \omega(\Delta_X - \Delta_Q) \right) \right. \\ & \quad \left. \Gamma_h \left(- \left(\tilde{\sigma}_j + m_B \frac{N_c}{kN_f - N_c} \right) + \tilde{m}_b - m_A + \omega(\Delta_X - \Delta_Q) \right) \right) \\ & \left(\prod_{i=1}^k \Gamma_h(\pm \rho_i + m_A N_f + \omega(\Delta_X - \Delta_M)) \right)\end{aligned}\tag{6.73}$$

We can now proceed to the dualization of the $U(k)$ sector as we did in the field theory analysis of the duality. However in that case, we had to introduce a perturbation that broke $U(k)$ into $U(1)^k$ and use field theory arguments to dualize the broken sector. Removing the perturbation in the superpotential, the gauge group recovers to $U(k)$ and we had to assume that this enhancement doesn't change the results obtained.

On the other hand, on the partition function we still have the unbroken sector $U(k)$ and we can use the following mathematical identity [46] to dualize it into a theory with chiral fields and no gauge group.

Let's define the partition function for a $U(N_c)$ theory with adjoint matter as

$$W_{N_c, K}(\mu_a, \nu_b, \tau, \lambda) = \frac{\Gamma_h(\tau)^{N_c}}{N_c!} \int \prod_{i=1}^{N_c} \frac{d\sigma_i}{\sqrt{-\omega_1 \omega_2}} e^{\frac{i\pi}{\omega_1 \omega_2} (2\lambda \sum_i \sigma_i - 2K \sum_i \sigma_i^2)} \prod_{i < j}^{N_c} \frac{\Gamma_h(\tau \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \prod_{i=1}^{N_c} \prod_{a,b=1}^{N_f} \Gamma_h(\mu_a + \sigma_i) \Gamma_h(\nu_b - \sigma_i) \quad (6.74)$$

where λ and K are the Fayet-Iliopoulos and Chern-Simons couplings respectively. The theory can then be dualized using the following identity [46]

$$W_{N_c, 0}(\mu_a, \nu_b, \tau, \lambda) = \prod_{j=0}^{N_c-1} \Gamma_h\left(\omega - \frac{\mu + \nu}{2} - j\tau \pm \lambda\right) \Gamma_h(j\tau + \mu + \nu) \Gamma_h((j+1)\tau) \exp\left(\frac{2\pi i}{\omega_1 \omega_2} N_c \frac{\lambda}{2} (\mu - \nu)\right) \quad (6.75)$$

Thus, the $U(k)$ sector is dual to a theory without gauge group and with $4k$ singlets, where $2k$ of them are charged under the topological symmetry. This is easily understood because the Fayet-Iliopoulos term λ is the charge of this symmetry.

We can apply this identity with the following values for the real masses

$$\begin{aligned} \mu_a &= m_A N_f + \omega(\Delta_X - \Delta_M) \\ \nu_a &= m_A N_f + \omega(\Delta_X - \Delta_M) \\ \tau &= \omega \Delta_X \\ \lambda &= \xi \\ N_c &= k \end{aligned} \quad (6.76)$$

We obtain the expression

$$\prod_{j=0}^{k-1} \Gamma_h(\omega - j\omega \Delta_X - (m_A N_f + \omega(\Delta_X - \Delta_M)) \pm \xi) \Gamma_h((j+1)\omega \Delta_X) \Gamma_h(2m_A N_f + 2\omega(\Delta_X - \Delta_M) + j\omega \Delta_X) \quad (6.77)$$

The terms on the first line can be rewritten as

$$\begin{aligned} & \prod_{j=0}^{k-1} \Gamma_h(\omega - j\omega \Delta_X - (m_A N_f + \omega((N_c + 1)\Delta_X - N_f(1 - \Delta_Q) - 1)) \pm \xi) = \\ &= \prod_{j=0}^{k-1} \Gamma_h(\pm \xi + \omega(2 + N_f(1 - \Delta_Q) - \Delta_X(N_c + 1 + j)) - m_A N_f) = \\ &= \prod_{j=0}^{k-1} \Gamma_h(\pm \xi + \omega(2 + N_f(1 - \Delta_Q) - \Delta_X(N_c + 1 + (k - 1 - j)) - m_A N_f) \\ &= \prod_{j'=1}^k \Gamma_h(\pm \xi + \omega(N_f(1 - \Delta_Q) - \Delta_X(N_c - j - 1)) - m_A N_f) \end{aligned} \quad (6.78)$$

using the explicit value of Δ_X .

These singlet fields (b_j, \tilde{b}_j) are mapped to the magnetic monopoles of the electric theory which have the following charges

	$U(kN_f - N_c) \times U(1)_{mir}$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
b_j	1_1	0	$-N_f$	1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$
\tilde{b}_j	1_{-1}	0	$-N_f$	-1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$

(6.79)

They are exactly the same fields we introduced in the field theory analysis of the duality in section 4.3.2.

We can repeat the procedure for one of the other singlets of (6.77) and we obtain

$$\begin{aligned}
& \prod_{j=0}^{k-1} \Gamma_h(2m_A N_f + 2\omega(\Delta_X - \Delta_M) + j\omega\Delta_X) = \\
& = \prod_{j=0}^{k-1} \Gamma_h(2m_A N_f + \omega(2 - j\Delta_X - 2\Delta_M))
\end{aligned} \tag{6.80}$$

After inserting this term back in the partition function we can use the mathematical identity $\Gamma_h(2\omega - x)\Gamma_h(x) = 1$ which is equivalent to the fact that if two chiral fields acquire a holomorphic mass they are integrated out and disappear from the partition function. Applying the identity to the following terms, they disappear from the partition function

$$\prod_{j=0}^{k-1} \Gamma_h(2m_A N_f + \omega(2 - j\Delta_X - 2\Delta_M)) \Gamma_h(-2m_A N_f + 2\omega(\Delta_M + j\Delta_X)) \tag{6.81}$$

There is an additional term that can be demonstrated that is equal to one. First suppose k is even

$$\begin{aligned}
\prod_{j=1}^k \Gamma_h\left(j \frac{2\omega}{k+1}\right) &= \prod_{j=1}^{k/2} \Gamma_h\left(j \frac{2\omega}{k+1}\right) \Gamma_h\left((k+1-j) \frac{2\omega}{k+1}\right) = \\
& \prod_{j=1}^{k/2} \Gamma_h\left(j \frac{2\omega}{k+1}\right) \Gamma_h\left(2\omega - j \frac{2\omega}{k+1}\right) = 1
\end{aligned} \tag{6.82}$$

where in the last line we used the property $\Gamma_h(x)\Gamma_h(2\omega - x) = 1$.

In case k is odd, we have

$$\begin{aligned}
\prod_{j=1}^k \Gamma_h\left(j \frac{2\omega}{k+1}\right) &= \prod_{j=1}^{\frac{k-1}{2}} \Gamma_h\left(j \frac{2\omega}{k+1}\right) \Gamma_h\left((k+1-j) \frac{2\omega}{k+1}\right) \Gamma_h\left(\frac{k+1}{2} \frac{2\omega}{k+1}\right) = \\
& \prod_{j=1}^{\frac{k-1}{2}} \Gamma_h\left(j \frac{2\omega}{k+1}\right) \Gamma_h\left(2\omega - j \frac{2\omega}{k+1}\right) \Gamma_h(\omega) = 1
\end{aligned} \tag{6.83}$$

where we used also the property $\Gamma_h(\omega) = 1$

6.2.5 Resulting partition function

$$\begin{aligned}
Z_{mag} = & \frac{1}{(kN_f - N_c)!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{kN_f - N_c - 1} \\
& \left(\prod_{j=0}^{k-1} \prod_a^{N_f} \prod_b^{N_f} \Gamma_h(\mu_a + \nu_b + j\omega\Delta_X) \right) \\
& \int \prod_{i=1}^{kN_f - N_c} \frac{d\sigma_i}{\omega_1 \omega_2} \int d\xi e^{\frac{\pi i}{\omega_1 \omega_2} 2\xi \sum \sigma_i} \prod_{i < j}^{kN_f - N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \\
& \left(\prod_{a,b}^{N_f} \prod_{j=1}^{kN_f - N_c} \Gamma_h\left(m_B \frac{N_c}{kN_f - N_c} - m_a - m_A + \omega(\Delta_X - \Delta_Q) + \tilde{\sigma}_j\right) \right. \\
& \quad \left. \Gamma_h\left(-m_B \frac{N_c}{kN_f - N_c} + \tilde{m}_b - m_A + \omega(\Delta_X - \Delta_Q) - \tilde{\sigma}_j\right) \right) \\
& \prod_{j'=0}^{k-1} \Gamma_h(\pm\xi + \omega(N_f(1 - \Delta_Q) - \Delta_X(N_c - j')) - m_A N_f)
\end{aligned} \tag{6.84}$$

The charges of the fields can be easily read from the arguments of the gamma functions and differ from the assignment of [28] only because of the baryonic charge of the quarks

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
q	$\overline{N_f}$	0	$\frac{N_c}{kN_f - N_c}$	-1	0	$\Delta_X - \Delta_Q$
\tilde{q}	0	N_f	$-\frac{N_c}{kN_f - N_c}$	-1	0	$\Delta_X - \Delta_Q$
X	0	0	0	0	0	Δ_X
M_j	N_f	$\overline{N_f}$	0	2	0	$2\Delta_Q + j\Delta_X$
b_j	0	0	0	$-N_f$	1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$
\tilde{b}_j	0	0	0	$-N_f$	-1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$

(6.85)

We can modify baryonic charge of the quarks by mixing the baryonic symmetry with the $U(1)$ of the $U(kN_f - N_c)$ by the following shift in $\tilde{\sigma}$

$$\tilde{\sigma}_i \longrightarrow \tilde{\sigma}_i - \frac{N_c}{kN_f - N_c} m_B \tag{6.86}$$

This shift is not traceless and in fact generates a mixed Chern-Simons term k_{BJ} with the topological symmetry which contributes to the partition function as

$$\int d\xi e^{\frac{2\pi i}{\omega_1 \omega_2} \xi (N_c m_B + \sum_i \tilde{\sigma}_i)} \tag{6.87}$$

After this shift, the charge of the theory are identical to the charges in [28]. Moreover, the appearance of the mixed Chern-Simons is expected because the $U(1)_{mirror}$ is the gauging of the topological symmetry which has the Fayet-Iliopoulos term ξ as a charge. The FI-term is associated to the $U(1)$ factor in the $U(kN_f - N_c)$ gauge group and as a result, we can understand the appearance of the mixed Chern-Simons term [28].

Alternative derivation

We can find the same partition function by modifying the charge assignment of the quarks before dualizing the $U(k)$ sector. Consider the partition function (6.73) and apply a traceless shift of σ and ρ such that it makes the quarks q, \tilde{q} uncharged under the baryonic symmetry and make the quarks b, \tilde{b} charged under it. It can be achieved by

$$\tilde{\sigma} \longrightarrow \tilde{\sigma} - m_B \frac{N_c}{kN_f - N_c} \quad \rho \longrightarrow \rho + m_B \frac{N_c}{k} \quad (6.88)$$

With this charge assignment the quark that will be dualized is different. The derivation after the dualization of the sector is identical except for the fact that with these real masses we have the additional mixed Chern-Simons term, now that $\mu - \nu \neq 0$

$$\exp \left(\frac{2\pi i}{\omega_1 \omega_2} N_c \xi (\mu - \nu) \right) = \exp \left(\frac{2\pi i}{\omega_1 \omega_2} \xi m_B N_c \right) \quad (6.89)$$

which match with the Fayet-Iliopoulos term we obtained by the shift in $\tilde{\sigma}$ of the previous section. The quarks are uncharged under the baryonic symmetry as in the charge assignment of [28], while the other charges are identical to the table of the previous section. The charges are given by

	$SU(N_f)_L$	$SU(N_f)_R$	$U(1)_B$	$U(1)_A$	$U(1)_J$	$U(1)_R$
q	$\overline{N_f}$	0	0	-1	0	$\Delta_X - \Delta_Q$
\tilde{q}	0	N_f	0	-1	0	$\Delta_X - \Delta_Q$
X	0	0	0	0	0	Δ_X
M_j	N_f	$\overline{N_f}$	0	2	0	$2\Delta_Q + j\Delta_X$
b_j	0	0	0	$-N_f$	1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$
\tilde{b}_j	0	0	0	$-N_f$	-1	$N_f(1 - \Delta_Q) + \Delta_X(j + 1 - N_c)$

(6.90)

The partition function with these charges and with the mixed Chern-Simons term is

$$\begin{aligned}
Z_{mag} = & \frac{1}{(kN_f - N_c)!} \Gamma_h(\Delta_X \omega; \omega_1, \omega_2)^{kN_f - N_c - 1} \\
& \left(\prod_{j=0}^{k-1} \prod_a^{N_f} \prod_b^{N_f} \Gamma_h(\mu_a + \nu_b + j\omega \Delta_X) \right) \\
& \int \prod_{i=1}^{kN_f - N_c} \frac{d\sigma_i}{\omega_1 \omega_2} \int d\xi e^{\frac{\pi i}{\omega_1 \omega_2} 2\xi (m_B N_c + \sum \sigma_i)} \prod_{i < j}^{kN_f - N_c} \frac{\Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j))}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \\
& \left(\prod_{a,b}^{N_f} \prod_{j=1}^{kN_f - N_c} \Gamma_h(-m_a - m_A + \omega(\Delta_X - \Delta_Q) + \tilde{\sigma}_j) \right. \\
& \quad \left. \Gamma_h(+\tilde{m}_b - m_A + \omega(\Delta_X - \Delta_Q) - \tilde{\sigma}_j) \right) \\
& \prod_{j'=0}^{k-1} \Gamma_h(\pm\xi + \omega(N_f(1 - \Delta_Q) - \Delta_X(N_c - j')) - m_A N_f)
\end{aligned} \tag{6.91}$$

Conclusions

In this thesis we analyzed the relations between Seiberg-like dualities in four and three dimensions. Even though Seiberg duality was discovered over twenty years ago, it is still an active area of research.

In particular, in 2013 was found a method to reduce duality from four to three dimensions. At the same time, it gave the possibility to find new dualities in three dimensions by the reduction of four ones.

For some dualities, the reduction process is theoretically well-understood in field theory, but for others a solid proof of the reduction is still missing.

This is due mainly to the different matter content in the magnetic theory between three and four dimensions. In fact, in three dimensions the magnetic theory features an additional set of singlet fields that are mapped to the magnetic monopoles of the electric theory and that interact with the magnetic monopoles of the magnetic theory through the superpotential. These singlet fields are not present in the original four dimensional magnetic theory.

It is necessary to overcome this difficulty in order to find a three dimensional duality. For example, in KSS dualities one has to introduce a deformation in the superpotential for the adjoint matter field in order to use mirror symmetry on the broken gauge group sector, obtaining the singlets fields. However, once the deformation is removed, mirror symmetry cannot be used anymore since it is not known for the initial unbroken gauge group. As a result, one has to made the assumption that the enhancement of the gauge group does not invalidate the results obtained with the deformation. This statement however requires a more detailed explanation which is not known yet.

On the other hand, the reduction process can be performed with the partition function approach we used in previous chapter. The advantage of this procedure in the case of KSS duality is that it does not require the introduction of a deformation in the superpotential. The dualization of the gauge sector can be made by using a mathematical identity which generates terms in the partition function that have the correct charges to be interpreted as the singlet fields of Kim-Park duality.

In this way we overcame the difficulties encountered in field theory and obtained Kim-Park duality for $SU(N_c)$ gauge group providing an independent check of

the results obtained with field theory arguments.

Moreover, the reduction of the duality on the partition function led us to the discovery of new integral identities between hyperbolic gamma function that are not yet demonstrated in mathematics. As a result, this could be one of the situations where physics could provide insights into mathematics.

Supersymmetry and superfields

A.1 Supersymmetry algebra

The supersymmetry algebra is an extension of the Poincarè group involving anticommutators together with commutators. Since it is not a ordinary Lie algebra, Coleman-Mandula theorem does not apply for theories that are invariant under it.

The supersymmetry algebra is divided into two subalgebras, the bosonic and fermionic part. The bosonic part contains Poincarè Lie algebra $(M_{\mu\nu}, P_\mu)$ while fermionic subalgebra is generated by the *supercharges* $(Q_\alpha^I, \bar{Q}_{\dot{\alpha}}^I)$ with $I = 1, \dots, \mathcal{N}$. When more than one pair of supercharges is present we refer to extended supersymmetry.

The supercharges sit in spinorial representations of the Lorentz group, respectively $(\frac{1}{2}, 0)$ and $(0, \frac{1}{2})$.

We will not repeat the bosonic subalgebra, since is given by the Poincarè Lie algebra. The fermionic generators satisfy anticommutation rules between themselves and commutation rules with bosonic generators. For this reason, the supersymmetry algebra is defined in mathematical literature as a graded Lie algebra with grade one.

The (anti)commutation rules in four dimensions are

$$[P_\mu, Q_\alpha^I] = 0 \quad (\text{A.1})$$

$$[P_\mu, \bar{Q}_{\dot{\alpha}}^I] = 0 \quad (\text{A.2})$$

$$[M_{\mu\nu}, Q_\alpha^I] = i(\sigma_{\mu\nu})_\alpha^\beta Q_\beta^I \quad (\text{A.3})$$

$$[M_{\mu\nu}, \bar{Q}_{\dot{\alpha}}^I] = i(\bar{\sigma}_{\mu\nu})_{\dot{\alpha}}^{\dot{\beta}} \bar{Q}_{\dot{\beta}}^I \quad (\text{A.4})$$

$$\{Q_\alpha^I, \bar{Q}_{\dot{\beta}}^J\} = 2\sigma_{\alpha\dot{\beta}}^\mu P_\mu \delta^{IJ} \quad (\text{A.5})$$

$$\{Q_\alpha^I, Q_\beta^J\} = \epsilon_{\alpha\beta} Z^{IJ} \quad Z^{IJ} = -Z^{JI} \quad (\text{A.6})$$

$$\{Q_{\dot{\alpha}}^I, Q_{\dot{\beta}}^J\} = \epsilon_{\dot{\alpha}\dot{\beta}} (Z^{IJ})^* \quad (\text{A.7})$$

This set of commutation rules can be found using symmetry arguments and

enforcing the consistency of the algebra using the graded Jacobi identity. It is important to stress the fact that Z^{IJ} are operators that span an invariant subalgebra: they are *central charges*. They play an important role especially in massive representations.

There is an additional symmetry that is not present in the previous commutation rules: R-symmetry. It is an automorphism of the algebra that act on the supercharges. For generic \mathcal{N} the R-Symmetry group is $U(\mathcal{N})$ ¹.

A.2 Representations

Since the supercharges do not commute with Lorentz generators, their action on a state will result in a state with different spin: they generate a symmetry between bosons and fermions.

Representations of supersymmetry contain particle with different spin but same mass and they are organized in supermultiplets. The mass of particles in the same multiplet must be the same because P^2 is still a Casimir operator of the supersymmetry algebra, while the Pauli-Lubanski operator W^2 isn't anymore.

Moreover, the supersymmetry algebra imposes that every state must have positive energy and that every supermultiplet must contain the same number of bosonic and fermionic degrees of freedom *on-shell*.

Various supermultiplets exist and their properties depend on the number of supercharges of the theory and on what they represent e.g matter, glue or gravity.

Massless supermultiplet are typically shorter than massive multiplet because in the massless case half of the supercharges are represented trivially. Massive representation of extended supersymmetry can be shortened in case some of the central charges of the algebra are equal to twice the mass of the multiplet. These states are usually called (ultra)short multiplet or BPS states.

We will introduce the multiplets that can be defined for $4d \mathcal{N} = 1$ theories and only later we will explain the differences with $3d \mathcal{N} = 2$ theories. Representations are similar because in both cases we have the same number of supercharges.

For four dimensional theories, we can define two different multiplet that are invariant under supersymmetry transformations. The matter or chiral multiplet contains a complex scalar (*squark*) and a Weyl fermion (*quark*). It identifies the matter content of the theory. The vector or gauge multiplet contains a Weyl fermion (*gaugino*) and a vector (*gluon or photon*). Particles in the same multiplet transform in the same representation of global or gauge symmetries. For this reason the gaugino cannot represent matter.

A representation of these multiplets on fields can be easily found using the *superspace* formalism that we will introduce in the next section. In this formalism it is possible to represent fields that are *off-shell*, in contrast with multiplets that we introduced previously that are *on-shell* since they represent states in Hilbert

¹This is not always true. For example for $\mathcal{N} = 4$ the R-symmetry group is given by $SU(4)$

space.

A.2.1 Superfields and superspace in four dimensions

Supersymmetry representations on fields can be found more systematically using the formulation of *superspace* instead of acting directly with supercharges and verifying that the algebra closes.

A simple formulation of superspace exist for theories with 4 supercharges while for theories with a bigger number of supercharges its definition is much more complex. We will be interested only in theories with 4 supercharges such as theories in 4D with $\mathcal{N} = 1$ or 3D with $\mathcal{N} = 2$.

Superspace can be seen as the extension of Minkowsky space with *fermionic coordinates* i.e. *Grassmann numbers* θ^α , $\bar{\theta}^{\dot{\alpha}}$. They anticommute between themselves and commute with everything else.

$$\{\theta^\alpha, \theta^\beta\} = 0 \quad \{\bar{\theta}^{\dot{\alpha}}, \bar{\theta}^{\dot{\beta}}\} = 0 \quad \{\theta^\alpha, \bar{\theta}^{\dot{\beta}}\} = 0 \quad \alpha, \dot{\alpha} = 1, 2 \quad (\text{A.8})$$

Derivation and integration in Grassmann variables are summarized by these rules

$$\partial_\alpha = \frac{\partial}{\partial \theta^\alpha} \quad \partial^\alpha = -\epsilon^{\alpha\beta} \partial_\beta \quad \bar{\partial}_{\dot{\alpha}} = \frac{\partial}{\partial \bar{\theta}^{\dot{\alpha}}} \quad \bar{\partial}^{\dot{\alpha}} = -\epsilon^{\dot{\alpha}\dot{\beta}} \partial_{\dot{\beta}} \quad \partial_\alpha \theta^\beta = \delta_\alpha^\beta \quad \partial_\alpha \bar{\theta}^{\dot{\alpha}} = 0 \quad (\text{A.9})$$

$$\int d\theta = 0 \quad \int d\theta \theta = 1 \quad d^2\theta = \frac{1}{2} d\theta^1 d\theta^2 \quad \int d^2\theta = \frac{1}{4} \epsilon^{\alpha\beta} \partial_\alpha \partial_\beta \quad (\text{A.10})$$

For a more detailed introduction on Grassmann numbers and their properties see [47].

Using Grassmann numbers we can write the anticommutators in the supersymmetry algebra as commutators defining $\theta Q = \theta^\alpha Q_\alpha$ and $\bar{\theta} \bar{Q} = \bar{\theta}^{\dot{\alpha}} \bar{Q}_{\dot{\alpha}}$

$$[\theta Q, \bar{\theta} \bar{Q}] = 2\theta^\mu \bar{\theta} P_\mu \quad , \quad [\theta Q, \theta Q] = [\bar{\theta} \bar{Q}, \bar{\theta} \bar{Q}] = 0 \quad (\text{A.11})$$

Using this trick we are able to represent the supersymmetry algebra as a Lie algebra. An element of the superPoincarè group can be found exponentiating the generators

$$G(x, \theta, \bar{\theta}, \omega) = \exp \left(ixP + i\theta Q + i\bar{\theta} \bar{Q} + \frac{1}{2} i\omega M \right) \quad (\text{A.12})$$

The superspace is defined as the 4+4 dimensions group coset

$$M_{4|1} = \frac{\text{SuperPoincarè}}{\text{Lorentz}} \quad (\text{A.13})$$

in analogy to Minkowsky space that can be defined as the coset between Poincarè and Lorentz groups.

A generic point in superspace is parametrized by $(x^\mu, \theta^\alpha, \bar{\theta}^{\dot{\alpha}})$. A superfield is a field in superspace i.e. function of the superspace coordinates. Since θ coordinates anticommute, the expansion of a superfield in fermionic coordinates stops at some point. The most general superfield $Y = Y(x, \theta, \bar{\theta})$ is given by

$$Y(x, \theta, \bar{\theta}) = f(x) + \theta\psi_1(x) + \bar{\theta}\bar{\psi}_2(x) + \theta\theta g_1(x) + \bar{\theta}\bar{\theta} g_2(x) \\ + \theta\sigma^\mu\theta v_\mu(x) + \theta\theta\bar{\theta}\bar{\lambda}(x) + \bar{\theta}\bar{\theta}\theta\rho(x) + \theta\theta\bar{\theta}\bar{\theta}s(x) \quad (\text{A.14})$$

fields with uncontracted θ such as $\psi_1, \psi_2, \lambda, \rho$ are spinors while v_μ is a vector.

Supercharges can be represented as differential operators that act on superfield. Their expression is

$$\begin{cases} Q_\alpha &= -i\partial_\alpha - \sigma_{\alpha\dot{\beta}}^\mu \bar{\theta}^{\dot{\beta}} \partial_\mu \\ \bar{Q}_{\dot{\alpha}} &= +i\bar{\partial}_{\dot{\alpha}} + \theta^\beta \sigma_{\beta\dot{\alpha}}^\mu \bar{\theta}^{\dot{\beta}} \partial_\mu \end{cases} \quad (\text{A.15})$$

An infinitesimal supersymmetry transformation on a superfield is defined by

$$\delta_{\epsilon, \bar{\epsilon}} Y = (i\epsilon Q + i\bar{\epsilon} \bar{Q}) Y \quad (\text{A.16})$$

The powerfulness of the superfield formalism is due to the fact that an integral in full superspace coordinates of a superfield is supersymmetric invariant.

$$\delta_{\epsilon, \bar{\epsilon}} \int d^4x d^2\theta d^2\bar{\theta} Y = \int d^4x d^2\theta d^2\bar{\theta} \delta_{\epsilon, \bar{\epsilon}} Y = 0 \quad (\text{A.17})$$

The first equality holds because the Grassmann measure is invariant under translation while the second is true because we can see that the variation of the superfield is either killed by the integration in the θ variables or is proportional to a spacetime derivative that does not contribute after integration in space.

Using this fact we can construct supersymmetric invariant lagrangians by integrating superfields in superspace. Clearly, in order to find a physically significant lagrangian we should choose the superfield we wish to integrate wisely. More importantly, we want to use irreducible representation of supersymmetry i.e. the supermultiplets we introduced before. We need to find conditions that can be imposed on a general superfield that are invariant under a supersymmetry transformation.

Chiral superfield

One way to achieve this goal is to find an operator that commute with the supercharges and annihilate the superfield. An example of such operator is the *covariant derivative*

$$\begin{cases} D_\alpha &= \partial_\alpha + i\sigma_{\alpha\dot{\beta}}^\mu \bar{\theta}^{\dot{\beta}} \partial_\mu \\ \bar{D}_{\dot{\alpha}} &= \bar{\partial}_{\dot{\alpha}} + i\theta^\beta \sigma_{\beta\dot{\alpha}}^\mu \bar{\theta}^{\dot{\beta}} \partial_\mu \end{cases} \quad (\text{A.18})$$

We can define a (anti)chiral superfield Φ

$$\bar{D}_\alpha \Phi = 0 \quad \text{chiral} \qquad D_\alpha \Psi = 0 \quad \text{anti-chiral} \qquad (\text{A.19})$$

This condition reduces the number of components of the superfield. It can be easily demonstrated that if Ψ is chiral, then $\bar{\Psi}$ is anti-chiral. As a result a chiral field cannot be real.

The expansion of a chiral fields in components is given by

$$\Phi(x, \theta, \bar{\theta}) = \phi(x) + \sqrt{2}\theta\psi(x) + i\theta\sigma^\mu\bar{\theta}\partial_\mu\phi(x) - \theta\theta F(x) - \frac{i}{\sqrt{2}}\theta\theta\partial_\mu\psi(x)\sigma^\mu\bar{\theta} - \frac{1}{4}\theta\theta\bar{\theta}\bar{\theta}(x) \qquad (\text{A.20})$$

We can see that a chiral field is composed by three fields: two complex scalars (ϕ and F) and a spinor (ψ).

The chiral superfield identifies the matter multiplet we introduced previously. It contains an additional bosonic field ($F(x)$) that is present because superfields provide an *off-shell* representation of supersymmetry and it is needed in order to close the algebra. It is called *auxiliary field* because it will not have kinetic terms in every Lagrangian that can be constructed.

Real or Vector Field

We can impose that the superfield is real. In this way we find the *real* or *vector* multiplet. Its general expression in component is messy and a simplification can be made noting that $\Phi + \bar{\Phi}$ is a vector superfield if Φ is chiral. Choosing an appropriate chiral field, the real superfield can be put in what is called Wess-Zumino gauge. We stress the fact that the Wess-Zumino gauge is not supersymmetric invariant: after a supersymmetry transformation the vector superfield acquire its general expression involving many other field components. In this gauge the vector superfield can be written as

$$V_{WZ}(x, \theta, \bar{\theta}) = \theta\sigma^\mu\bar{\theta}v_\mu(x) + i\theta\theta\bar{\theta}\bar{\lambda}(x) - i\bar{\theta}\bar{\theta}\theta\lambda(x) + \frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}D(x) \qquad (\text{A.21})$$

The vector superfields represents the vector multiplet (which contains radiation) and similarly to the chiral superfields contains an auxiliary field ($D(x)$).

A.2.2 R-symmetry

R-symmetry was first introduced with the supersymmetry algebra. For the theories we will consider in superspace it is given by a global $U(1)_R$. It is defined by as a transformation of the Grassmann coordinates

$$\theta \rightarrow e^{i\alpha}\theta \qquad \bar{\theta} \rightarrow e^{-i\alpha}\bar{\theta} \qquad (\text{A.22})$$

α parametrizes the transformation. As a result supercharges transform under the transformation

$$Q \rightarrow e^{-i\alpha}Q \qquad \bar{Q} \rightarrow e^{+i\alpha}\bar{Q} \qquad (\text{A.23})$$

From this we find the commutator relations between supercharges and R-symmetry generator R

$$[R, Q] = -Q \quad [R, \bar{Q}] = \bar{Q} \quad (\text{A.24})$$

The R-charge of a superfield is defined by

$$Y(x, \theta, \bar{\theta}) \rightarrow e^{iR_Y \alpha} Y(x, \theta, \bar{\theta}) \quad (\text{A.25})$$

Different component field in the superfield have different R-charge and are related because of A.24. For a chiral field we have

$$R[\phi] = R[\Phi] \quad R[\psi] = R[\Phi] - 1 \quad R[F] = R[\Phi] - 2 \quad (\text{A.26})$$

The corresponding antichiral field carry opposite charges.

A.3 Supersymmetric actions

We will use the property we introduced in A.17 to generate supersymmetric invariant lagrangians. We start our analysis with chiral superfields. Since lagrangians are quadratic in the fields and must be real, the simplest kinetic term for a chiral superfield is given by $\bar{\Phi}\Phi$.

$$\mathcal{L}_{kin} = \int d^2\theta d^2\bar{\theta} \bar{\Phi}\Phi = \partial_\mu \bar{\phi} \partial^\mu \phi + \frac{i}{2} (\partial_\mu \psi \sigma^\mu \bar{\psi} - \psi \sigma^\mu \partial_\mu \bar{\psi}) + \bar{F}F + \text{total derivative} \quad (\text{A.27})$$

which gives the correct kinetic terms for a scalar and a spinor. The auxiliary field doesn't have kinetic terms as predicted.

Many action can be find using a generalization of the equation above. It is called *Kahler* potential

$$K(\bar{\Phi}, \Phi) = \sum_{m,n=1}^{\infty} c_{m,n} \bar{\Phi}^m \Phi^n \quad \text{where} \quad c_{m,n} = c_{n,m}^* \quad (\text{A.28})$$

The condition on the coefficient is imposed by the requirement of a real lagrangian.

Another way of finding supersymmetric actions is by integrating *chiral* superfields in half-superspace coordinates. We define the *superpotential* to be a holomorphic function of Φ

$$\mathcal{L}_{int} = \int d^2\theta d^2\bar{\theta} W(\Phi) + \int d^2\bar{\theta} \bar{W}(\bar{\Phi}) = \sum_{i=1}^{\infty} \int d^2\theta \lambda_i \Phi^i + \int d^2\bar{\theta} \lambda_i^\dagger \bar{\Phi}^i \quad (\text{A.29})$$

The hermitian conjugate was added in order to have a real lagrangian.

Mixed terms with product of chiral and anti-chiral superfield are not present since they would be generic superfields and would not yield a supersymmetric

lagrangian. In fact if $W(\Phi)$ is holomorphic and Φ is a chiral superfield, $W(\Phi)$ is a chiral superfield

$$\bar{D}_{\dot{\alpha}}W(\Phi) = \frac{\partial W}{\partial \Phi} \bar{D}_{\dot{\alpha}}\Phi + \frac{\partial W}{\partial \bar{\Phi}} \bar{D}_{\dot{\alpha}}\bar{\Phi} = 0 \quad (\text{A.30})$$

and yield a proper lagrangian upon integration in $d^2\theta$.

Since the superpotential is integrated only in half superspace coordinates it need to be charged in an opposite way with respect to the integration measure under R-symmetry. Remembering that

$$R[\theta] = 1 \quad [\bar{\theta}] = -1 \quad R[d\theta] = -1 \quad R[d\bar{\theta}] = 1 \quad (\text{A.31})$$

It's easy to see that

$$R[W(\Phi)] = 2 \quad R[\bar{W}(\bar{\Phi})] = -2 \quad (\text{A.32})$$

For this reason in most situations the superpotential fix the supercharges of the fields.

The lagrangian of super Yang-Mills theories is given by

$$\mathcal{L}_{SYM} = \frac{1}{32\pi i} \left(\int d^2\theta \left(\frac{\theta_{YM}}{2\pi} + \frac{4\pi i}{g^2} \right) W_{\alpha} W^{\alpha} \right) = \quad (\text{A.33})$$

$$= \text{Tr} \left[-\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - i\lambda\sigma^{\mu} D_{\mu}\bar{\lambda} + \frac{1}{2} D^2 \right] + \frac{\theta_{YM}}{32\pi^2} g^2 \text{Tr} F_{\mu\nu} \tilde{F}^{\mu\nu} \quad (\text{A.34})$$

where we defined the chiral superfield W_{α} as

$$W_{\alpha} = -\frac{1}{4} \bar{D}\bar{D} \left(e^{-2gV} D_{\alpha} e^{2gV} \right) \quad \bar{W}_{\dot{\alpha}} = -\frac{1}{4} D D \left(e^{2gV} \bar{D}_{\dot{\alpha}} V e^{-2gV} \right) \quad (\text{A.35})$$

It can be demonstrated that W_{α} is chiral and is invariant under the supergauge transformation $V \rightarrow V + \bar{\Phi} + \Phi$ while the vector superfield V was not.

From a perturbative point of view the inclusion of the term proportional to $\theta_{YM} \text{Tr} F_{\mu\nu} \tilde{F}^{\mu\nu}$ has no effect since it is proportional to a total derivative. It is a parity violating term that differs from zero only in non trivial topological configurations of the field (instantons).

The matter lagrangian we introduced is not invariant under gauge transformation. The correct gauge invariant lagrangian is given by

$$\mathcal{L}_{matter} = \int d^2\theta d^2\bar{\theta} \bar{\Phi} e^{2gV} \Phi \quad (\text{A.36})$$

The superpotential is not automatically invariant under gauge transformation. As a result only certain expression are allowed.

There's an additional supersymmetric invariant lagrangian that can be constructed in a gauge theory when the gauge group contains abelian factors. It is called Fayet-Iliopoulos term and can be present for every ideal A of the gauge group

$$\mathcal{L}_{FI} = \sum_A \xi_A \int d^2\theta d^2\bar{\theta} V^A = \frac{1}{2} \sum_A \xi_A D^A \quad (\text{A.37})$$

Scalar potential

Supersymmetric field theories contain various scalar fields that can acquire non-zero vacuum expectation values. The scalar potential is the only term in the Lagrangian and in the Hamiltonian that can differ from zero since derivatives of the scalar fields have to be zero in order to preserve the Lorentz invariance of the vacuum. As a result, the minima of the scalar potential are in one-to-one correspondence with the states of minimal energy of the theory.

The scalar potential for $4D \mathcal{N} = 1$ gauge theories with matter reads

$$V(\phi_i, \bar{\phi}_j) = F\bar{F} + \frac{1}{2}D^2 \stackrel{on-shell}{=} \frac{\partial W}{\partial \phi_i} \frac{\partial \bar{W}}{\partial \bar{\phi}_i} + \frac{g^2}{2} \sum_a |\bar{\phi}_j (T^a)_i^j \phi^j + \xi^a|^2 \geq 0 \quad (\text{A.38})$$

ξ^a is the Fayet-Iliopoulos coefficient and differs from zero only if the gauge group has abelian factors. The last equality is valid since D and F are auxiliary fields with no dynamics whose value is set by their equations of motion

$$\bar{F}_i = \frac{\partial \bar{W}}{\partial \bar{\phi}_i} \quad D^a = -g\bar{\phi} T^a \phi - g\xi^a \quad (\text{A.39})$$

It can be demonstrated that the scalar potential is a positive definite function. The zeroes of the scalar potential can be found, if present, by solving separately the F -term and D -term equations

$$F = 0 \quad D^a = 0 \quad (\text{A.40})$$

Appendix **B**

Hypergeometric gamma functions

In this appendix we list the basic definitions and the mathematical identities needed for our work. A more detailed introduction on hypergeometric gamma functions and their properties can be found in [48, 46].

B.1 Elliptic hypergeometric functions

The elliptic functions we used in the superconformal index are defined by

$$\begin{aligned}\Gamma_e(y; p, q) &= \prod_{j,k \geq 0} \frac{1 - y^{-1} p^{j+1} q^{k+1}}{1 - y p^j q^k} \\ \theta(z; p) &= \prod_{j \geq 0} (1 - z p^j)(1 - z^{-1} p^{j+1}) \\ (x; p) &= \prod_{j \geq 0} (1 - x p^j)\end{aligned}\tag{B.1}$$

The single particle index for the vector field reads

$$i_E^V(p^n, q^n) = - \left(\frac{p^n}{1 - p^n} + \frac{q^n}{1 - q^n} \right)\tag{B.2}$$

The following identities can be used to calculate the Plethystic exponential for the vector field

$$\exp \left(\sum_{n=1}^{\infty} \frac{1}{n} i_E^V(p^n, q^n) \right) = (p; p)(q; q)\tag{B.3}$$

$$\begin{aligned}\exp \left(\sum_{n=1}^{\infty} \frac{1}{n} i_E^V(p^n, q^n) \right) (z^n + z^{-n}) &= \frac{\theta(z; p)\theta(z^{-1}; q)}{1 - z^2} \\ &= \frac{1}{(1 - z)(1 - z^{-1})\Gamma_e(z; p, q)\Gamma_e(z^{-1}; p, q)}\end{aligned}\tag{B.4}$$

While the following is used for chiral fields

$$\Gamma_e(z; p, q) = \exp \left(\sum_{n=1}^{\infty} \frac{1}{n} \frac{z^n - \left(\frac{pq}{z}\right)^n}{(1-p^n)(1-q^n)} \right) \quad (\text{B.5})$$

B.2 Hyperbolic gamma function

The hyperbolic gamma function can be defined in many different ways [46]. The following is the most explicit

$$\Gamma_h(z; \omega_1, \omega_2) = \exp \left(\pi i \frac{(2z - \omega_1 - \omega_2)^2}{8\omega_1\omega_2} - \pi i \frac{(\omega_1^2 + \omega_2^2)}{24\omega_1\omega_2} \right) \frac{(\exp(-2\pi i(z - \omega_2)/\omega_1); \exp(2\pi i\omega_2/\omega_1))_{\infty}}{(\exp(-2\pi i z/\omega_2); \exp(-2\pi i\omega_1/\omega_2))_{\infty}} \quad (\text{B.6})$$

Elliptic to hyperbolic The following mathematical identities will be used to find an expression in the limit of the shrinking circle. For chiral fields we will use [46]

$$\lim_{r \rightarrow 0^+} \Gamma_e(e^{2irz}; e^{2\pi ir\omega_1}, e^{2\pi ir\omega_2}) \sim e^{-\frac{i\pi^2}{6r\omega_1\omega_2}(z-\omega)} \Gamma_h(z; \omega_1, \omega_2) \quad (\text{B.7})$$

While for the vector field in the adjoint representation we will use this identity, which follows from the $SL(2, \mathbb{Z})$ properties of the $\theta(z; p)$ function [21]

$$\begin{aligned} \lim_{r \rightarrow 0} \frac{(p; p)^{r_G} (q; q)^{r_G}}{|W|} \oint_{T^{r_G}} \prod_{j=1}^{r_G} \frac{dz_j}{2\pi i z_j} \prod_{\alpha \in R_+} \theta(e^{\alpha}; p) \theta(e^{-\alpha}; q) \sim \\ \sim \exp \left(-\frac{i\pi\omega|G|}{6r\omega_1\omega_2} \right) \frac{1}{|W|} \int \prod_{j=1}^{r_G} \frac{d\sigma_j}{\sqrt{-\omega_1\omega_2}} \prod_{\alpha \in R_+} \frac{1}{\Gamma_h(\alpha(\sigma)) \Gamma_h(-\alpha(\sigma_j))} \end{aligned} \quad (\text{B.8})$$

where $|G|$ is the number of generators of the group G , r_G its rank and $|W|$ is the order of the Weyl symmetry of the group. The roots α are taken only taken positive.

Large mass limit For the limit of large mass we will use the following formula [46]

$$\lim_{t \rightarrow \infty} \Gamma_h(z + t; \omega_1, \omega_2) = \exp \left[\text{sign}(t) \frac{\pi i}{2\omega_1\omega_2} \left((z + t - \omega)^2 - \frac{\omega_1^2 + \omega_2^2}{12} \right) \right] \quad (\text{B.9})$$

Appendix **C**

Index and partition function for the electric theory

C.1 Calculation of the superconformal index

C.1.1 Contribution from the vector field

The Plethystic exponential for the index of the vector (6.12) is given by

$$\begin{aligned}
 I_E^V(p, q, z) &= \exp \left(\sum_{n=1}^{\infty} \frac{1}{n} i_E^{Vett}(p^n, q^n, z^n) \right) \stackrel{def}{=} \\
 &\exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) \left(\left(\sum_{1 \leq i, j \leq N_c} \frac{z_i^n}{z_j^n} \right) - 1 \right) \right) = \\
 &= \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) \left(\left(\sum_{\substack{1 \leq i, j \leq N_c \\ i \neq j}} \frac{z_i^n}{z_j^n} \right) + \left(\sum_{i=1}^{N_c} 1 \right) - 1 \right) \right) = \\
 &= \left[\exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) \left(\left(\sum_{\substack{1 \leq i, j \leq N_c \\ i \neq j}} \frac{z_i^n}{z_j^n} \right) \right) \right) \right] \times \\
 &\quad \times \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) (N_c - 1) \right) =
 \end{aligned} \tag{C.1}$$

which can be rewritten more compactly as

$$\left[\prod_{\substack{1 \leq i, j \leq N_c \\ i \neq j}} \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} i_E^V(p^n, q^n) \frac{z_i^n}{z_j^n} \right) \right] \left[\exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} i_E^V(p^n, q^n) \right) \right]^{N_c-1} \tag{C.2}$$

We can apply directly the mathematical identity (B.3) to the last term obtaining

$$(p; p)^{N_c-1} (q; q)^{N_c-1}$$

Before applying the identity (B.4) to the first term of (C.2) we need to note that

$$\prod_{\substack{1 \leq i, j \leq N_c \\ i \neq j}} \frac{z_i^n}{z_j^n} = \prod_{1 \leq i < j \leq N_c} \left(\frac{z_i^n}{z_j^n} + \frac{z_j^n}{z_i^n} \right)$$

Using (B.4) we obtain

$$\begin{aligned} & \prod_{1 \leq i < j \leq N_c} \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} \left(\frac{p^n}{1-p^n} + \frac{q^n}{1-q^n} \right) \left(\frac{z_i^n}{z_j^n} + \frac{z_j^n}{z_i^n} \right) \right) = \\ & \prod_{1 \leq i < j \leq N_c} \exp \left(\sum_{n=1}^{\infty} -\frac{1}{n} i_E^V(p^n, q^n) \left(\frac{z_i^n}{z_j^n} + \frac{z_j^n}{z_i^n} \right) \right) \times \\ & \times \prod_{1 \leq i < j \leq N_c} \frac{1}{\left(1 - \frac{z_i}{z_j}\right) \left(1 - \frac{z_j}{z_i}\right) \Gamma_e\left(\frac{z_i}{z_j}; p, q\right) \Gamma_e\left(\frac{z_j}{z_i}; p, q\right)} \end{aligned}$$

Consider both terms, the full contribution to the index is given by

$$\begin{aligned} & (p; p)^{N_c-1} (q; q)^{N_c-1} \prod_{1 \leq i < j \leq N_c} \frac{1}{\left(1 - \frac{z_i}{z_j}\right) \left(1 - \frac{z_j}{z_i}\right) \Gamma_e\left(\frac{z_i}{z_j}; p, q\right) \Gamma_e\left(\frac{z_j}{z_i}; p, q\right)} \\ & (p; p)^{N_c-1} (q; q)^{N_c-1} \frac{1}{\Delta(z) \Delta(z^{-1})} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_e\left(\frac{z_i}{z_j}; p, q\right) \Gamma_e\left(\frac{z_j}{z_i}; p, q\right)} \end{aligned}$$

C.1.2 Contribution from the adjoint matter

The single particle index of the adjoint matter is

$$i_E^X(p, q, z) = \frac{1}{(1-p)(1-q)} \left((pq)^{\frac{R_X}{2}} - (pq)^{1-\frac{R_X}{2}} \right) \left(\left(\sum_{1 \leq i, j \leq N_c} \frac{z_i}{z_j} \right) - 1 \right) \quad (C.3)$$

similarly to the vector field index, we separate the terms depending on the presence of z_i

$$\begin{aligned} I_E^X(p, q, z) &= \left[\exp \left((N_c - 1) \sum_{n=1}^{\infty} \frac{1}{n} \frac{(pq)^{\frac{R_X}{2}n} - (pq)^{\left(1-\frac{R_X}{2}\right)n}}{(1-p^n)(1-q^n)} \right) \right] \times \\ & \times \left[\prod_{1 \leq i < j \leq N_c} \exp \left(\sum_{n=1}^{\infty} \frac{1}{n} \left((pq)^{\frac{R_X}{2}n} - (pq)^{\left(1-\frac{R_X}{2}\right)n} \right) \left(\frac{z_i^n}{z_j^n} + \frac{z_j^n}{z_i^n} \right) \right) \right] \quad (C.4) \end{aligned}$$

These terms can be written in terms of elliptic gamma functions using (B.5). In order to use it on the first factor, we define $y = (pq)^{\frac{R_X}{2}}$ and we find

$$\left[\exp \left(\sum_{n=1}^{\infty} \frac{1}{n} \frac{(y)^n - \left(\frac{pq}{y}\right)^n}{(1-p^n)(1-q^n)} \right) \right]^{(N_c-1)} = \Gamma_e\left((pq)^{\frac{R_X}{2}}; p, q\right)^{(N_c-1)} \quad (C.5)$$

The second term is a little more involved since we have to rearrange the terms in the numerator of the fraction

$$\begin{aligned} & \left((pq)^{\frac{R_X}{2}n} - (pq)^{\left(1-\frac{R_X}{2}\right)n} \right) \left(\frac{z_i^n}{z_j^n} + \frac{z_j^n}{z_i^n} \right) = \\ & \left((pq)^{\frac{R_X}{2}n} \frac{z_i^n}{z_j^n} - (pq)^{\left(1-\frac{R_X}{2}\right)n} \frac{z_j^n}{z_i^n} \right) + \left((pq)^{\frac{R_X}{2}n} \frac{z_j^n}{z_i^n} - (pq)^{\left(1-\frac{R_X}{2}\right)n} \frac{z_i^n}{z_j^n} \right) \end{aligned} \quad (\text{C.6})$$

in order to apply (B.5) we need to perform the following change of variables

$$y = (pq)^{\frac{R_X}{2}} \frac{z_i}{z_j} \quad y' = (pq)^{\frac{R_X}{2}} \frac{z_j}{z_i} \quad (\text{C.7})$$

which results in the expression

$$\prod_{1 \leq i < j \leq N_c} \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_i}{z_j} \right) \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_j}{z_i} \right) \quad (\text{C.8})$$

Combining the two factors, the contribution from the adjoint matter is

$$\Gamma_e \left((pq)^{\frac{R_X}{2}}; p, q \right)^{N_c-1} \prod_{1 \leq i < j \leq N_c} \Gamma_e \left((pq)^{\frac{R_X}{2}} \frac{z_i}{z_j} \right) \Gamma_e \left((pq)^s \frac{z_j}{z_i} \right) \quad (\text{C.9})$$

C.1.3 Contribution from the quarks

The single particle index for the quarks reads

$$\begin{aligned} i_E^{Q, \tilde{Q}}(p, q, v, y, \tilde{y}) = & \frac{1}{(1-p)(1-q)} \sum_{i=1}^{N_f} \sum_{j=1}^{N_c} \left((pq)^{\frac{1}{2}R_Q} v y_i z_j - (pq)^{1-\frac{1}{2}R_Q} v^{-1} y_i^{-1} z_j^{-1} \right. \\ & \left. + (pq)^{\frac{1}{2}R_Q} v^{-1} \tilde{y}_i z_j^{-1} - (pq)^{1-\frac{1}{2}R_Q} v \tilde{y}_i^{-1} z_j \right) \end{aligned} \quad (\text{C.10})$$

which can be simplified by the following transformations

$$(pq)^{\frac{R_Q}{2}} v y z_j \rightarrow y_{i,j} \quad \left((pq)^{-\frac{R_Q}{2}} v y z_j \right)^{-1} \rightarrow \tilde{y}_{i,j} \quad (\text{C.11})$$

which results in

$$\begin{aligned} I_E^{Q, \tilde{Q}}(p, q, y, \tilde{y}) = & \prod_{1 \leq j \leq N_c} \prod_{1 \leq i \leq N_f} \exp \left[\sum_{n=1}^{\infty} -\frac{1}{n} \frac{1}{(1-p^n)(1-q^n)} \right. \\ & \left. \left(\left((y_i z_j)^n - \left(\frac{pq}{y_i z_j} \right)^n \right) + \left(\frac{1}{(\tilde{y}_i z_j)^n} - (pq \tilde{y}_i z_j)^n \right) \right) \right] \end{aligned} \quad (\text{C.12})$$

and using the identity (B.5) we obtain

$$I_E^{Q, \tilde{Q}}(p, q, v, y, \tilde{y}, z) = \prod_{1 \leq j \leq N_c} \prod_{1 \leq i \leq N_f} \Gamma_e \left((pq)^{\frac{R_Q}{2}} v y_i z_j \right) \Gamma_e \left((pq)^{\frac{R_Q}{2}} v^{-1} \tilde{y}_i^{-1} z_j^{-1} \right) \quad (\text{C.13})$$

C.2 Reduction of the index to the partition function

Vector field

$$\begin{aligned} \lim_{r \rightarrow 0} \frac{(p; p)^{N_c-1} (q; q)^{N_c-1}}{N_c!} \oint_{T^{N_c-1}} \prod_{j=1}^{N_c-1} \frac{dz_j}{2\pi i z_j} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_e\left(\frac{z_i}{z_j}\right) \Gamma_e\left(\frac{z_j}{z_i}\right)} \sim \\ \sim \exp\left(-\frac{i\pi\omega(N_c^2-1)}{6r\omega_1\omega_2}\right) \frac{1}{N_c!} \int \prod_{j=1}^{N_c-1} \frac{d\sigma_j}{\sqrt{-\omega_1\omega_2}} \prod_{1 \leq i < j \leq N_c} \frac{1}{\Gamma_h(\pm(\sigma_i - \sigma_j))} \end{aligned} \quad (C.14)$$

Adjoint matter

$$\begin{aligned} \Gamma_e((pq)^{\frac{\Delta_X}{2}})^{N_c-1} &= \Gamma_e\left(e^{2\pi i r \frac{\Delta_X}{2}(\omega_1+\omega_2)}\right)^{N_c-1} = \Gamma_e\left(e^{2\pi i r \Delta_X \omega}\right)^{N_c-1} = \\ &= \left[\exp\left(-\frac{i\pi}{6r\omega_1\omega_2}(\omega\Delta_X - \omega)\right)\right]^{N_c-1} \Gamma_h(\omega\Delta_X; \omega_1, \omega_2)^{N_c-1} \\ \Gamma_e\left((pq)^{\frac{\Delta_X}{2}}\left(\frac{z_i}{z_j}\right)\right) \Gamma_e\left((pq)^{\frac{\Delta_X}{2}}\left(\frac{z_j}{z_i}\right)\right) &= \\ &= \Gamma_e\left(e^{2\pi i r \frac{\Delta_X}{2}(\omega_1+\omega_2)} e^{2\pi i r(\sigma_i - \sigma_j)}\right) \Gamma_e\left(e^{2\pi i r \frac{\Delta_X}{2}(\omega_1+\omega_2)} e^{2\pi i r(\sigma_j - \sigma_i)}\right) = \\ &= \Gamma_e\left(e^{2\pi i r(\Delta_X \omega + \sigma_i - \sigma_j)}\right) \Gamma_e\left(e^{2\pi i r(\Delta_X \omega + \sigma_j - \sigma_i)}\right) \\ &\sim \exp\left(-\frac{i\pi}{6r\omega_1\omega_2}(2\omega\Delta_X + (\sigma_i - \sigma_j) + (\sigma_j - \sigma_i) - 2\omega)\right) \Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j)) \\ &\sim \exp\left(-\frac{i\pi}{6r\omega_1\omega_2}(2\omega(\Delta_X - 1))\right) \Gamma_h(\Delta_X \omega \pm (\sigma_i - \sigma_j)) \end{aligned} \quad (C.15)$$

Quarks

$$\begin{aligned} \prod_{a,b}^{N_f} \prod_j^{N_c} \Gamma_e\left((pq)^{\frac{R_Q}{2}} v y_a z_j\right) \Gamma_e\left((pq)^{\frac{R_Q}{2}} v^{-1} \tilde{y}_b^{-1} z_j^{-1}\right) &= \\ &= \Gamma_e\left(e^{2\pi i r \left(\frac{R_Q}{2}(\omega_1+\omega_2) + (m_a + m_B + \sigma_j)\right)}\right) \Gamma_e\left(e^{2\pi i r \left(\frac{R_Q}{2}(\omega_1+\omega_2) + (-\tilde{m}_b - m_B - \sigma_j)\right)}\right) = \\ &= \exp\left(-\frac{i\pi}{6r\omega_1\omega_2}((\omega R_Q + m_a + m_B + \sigma_j - \omega) + (\omega R_Q - \tilde{m}_b - m_B - \sigma_j - \omega))\right) \\ &\quad \times \Gamma_h(\omega R_Q + m_a + m_B + \sigma_j) \Gamma_h(\omega R_Q - \tilde{m}_b - m_B - \sigma_j) = \\ &= \exp\left(-\frac{i\pi}{6r\omega_1\omega_2}(2\omega(R_Q - 1) + m_a - \tilde{m}_b)\right) \Gamma_h(\mu_a + \sigma_j) \Gamma_h(\nu_b - \sigma_j) \end{aligned} \quad (C.16)$$

where we defined

$$\mu_a = \omega\Delta + m_a + m_B \quad \nu_b = \omega\Delta - \tilde{m}_b - m_B \quad (C.17)$$

Appendix D

Superconformal index and partition function for the magnetic theory

D.1 Reduction of the index to the partition function

Mesons

$$\begin{aligned}
& \prod_{i=1}^{N_f} \prod_{j=1}^{N_f} \prod_{l=0}^{k-1} \Gamma_e((pq)^{r+ls} y_i \tilde{y}_j^{-1}; p, q) = \\
& \prod_{i=1}^{N_f} \prod_{j=1}^{N_f} \prod_{l=0}^{k-1} \Gamma_e\left(\exp(2\pi i r [(2\omega)(r+ls) + (m_i - \tilde{m}_j)]); p, q\right) \sim \\
& \stackrel{r \rightarrow 0}{\sim} \prod_{i=1}^{N_f} \prod_{j=1}^{N_f} \prod_{l=0}^{k-1} \exp\left(\frac{-i\pi}{6r\omega_1\omega_2} (2\omega(r+ls) + m_i - \tilde{m}_j - \omega)\right) \Gamma_h(\omega(2\Delta_Q + l\Delta_X) + m_i - \tilde{m}_j) = \\
& = \exp\left[\frac{-i\pi}{6r\omega_1\omega_2} \left(N_f^2 \left(\sum_{l=0}^{k-1} 2\omega(r+ls - \frac{1}{2})\right) + N_f \left(\sum_{l=0}^{k-1} \sum_i^{N_f} m_i - \tilde{m}_i\right)\right)\right] \\
& \quad \prod_{i=1}^{N_f} \prod_{j=1}^{N_f} \prod_{l=0}^{k-1} \Gamma_h(\omega(2\Delta_Q + l\Delta_X) + m_i - \tilde{m}_j) \\
& = \exp\left[\frac{-i\pi}{6r\omega_1\omega_2} \left(N_f^2 \left(\sum_{l=0}^{k-1} 2\omega(\Delta_Q - \frac{1}{2}) + \omega l\Delta_X\right) + N_f \left(\sum_{l=0}^{k-1} \sum_i^{N_f} m_i - \tilde{m}_i\right)\right)\right] \\
& \quad \prod_{i=1}^{N_f} \prod_{j=1}^{N_f} \prod_{l=0}^{k-1} \Gamma_h(\omega(2\Delta_Q + l\Delta_X) + m_i - \tilde{m}_j)
\end{aligned} \tag{D.1}$$

Chiral fields

$$\begin{aligned}
& \prod_{1 \leq j \leq \tilde{N}_c} \prod_{1 \leq i \leq N_f} \Gamma_e((pq)^{\frac{1}{2}\Delta_q} \tilde{v} y_i^{-1} \tilde{z}_j; p, q) \Gamma_e((pq)^{\frac{1}{2}\Delta_q} \tilde{v}^{-1} \tilde{y}_i \tilde{z}_j^{-1}; p, q) = \\
& = \prod_{1 \leq j \leq \tilde{N}_c} \prod_{1 \leq i \leq N_f} \Gamma_e \left(\exp \left(2\omega \left(\frac{1}{2}\Delta_q \right) + \tilde{m}_B - m_i + \tilde{\sigma}_j \right); p, q \right) \\
& \quad \Gamma_e \left(\exp \left(2\omega \left(\frac{1}{2}\Delta_q \right) - \tilde{m}_B + \tilde{m}_i - \tilde{\sigma}_j \right); p, q \right) = \\
& \quad \Gamma_h(\omega\Delta_q + \tilde{m}_B - m_i + \tilde{\sigma}_j) \Gamma_h(\omega\Delta_q - \tilde{m}_B + \tilde{m}_i - \tilde{\sigma}_j) = \\
& = \exp \left[\frac{-i\pi}{6r\omega_1\omega_2} \left(2N_f \tilde{N}_c \omega(\Delta_q - 1) + \tilde{N}_c \left(\sum_{i=1}^{N_f} \tilde{m}_i - m_i \right) \right) \right] \Gamma_h(\mu_i + \tilde{\sigma}_j) \Gamma_h(\nu_i - \tilde{\sigma}_j)
\end{aligned} \tag{D.2}$$

where we defined the real masses

$$\mu_i = \omega\Delta_q + \tilde{m}_B - m_i \quad \nu_i = \omega\Delta_q - \tilde{m}_B + \tilde{m}_i$$

Vector field

$$\begin{aligned}
& \lim_{r \rightarrow 0} \frac{(p; p)^{N_c-1} (q; q)^{N_c-1}}{N_c!} \oint_{T^{\tilde{N}_c-1}} \prod_{j=1}^{\tilde{N}_c-1} \frac{dz_j}{2\pi i z_j} \prod_{1 \leq i < j \leq \tilde{N}_c} \frac{1}{\Gamma_e(\frac{z_i}{z_j}) \Gamma_e(\frac{z_j}{z_i})} \sim \\
& \sim \exp \left(-\frac{i\pi\omega(\tilde{N}_c^2 - 1)}{6r\omega_1\omega_2} \right) \frac{1}{\tilde{N}_c!} \int \prod_{j=1}^{\tilde{N}_c-1} \frac{d\sigma_j}{\sqrt{-\omega_1\omega_2}} \prod_{1 \leq i < j \leq \tilde{N}_c} \frac{1}{\Gamma_h(\pm(\sigma_i - \sigma_j))}
\end{aligned} \tag{D.3}$$

Adjoint matter field

$$\begin{aligned}
& \Gamma_e((pq)^{\frac{\Delta_X}{2}})^{N_c-1} = \Gamma_e \left(\exp \left[2\pi i r \frac{\Delta_X}{2} (\omega_1 + \omega_2) \right] \right)^{\tilde{N}_c-1} = \Gamma_e(e^{2\pi i r \Delta_X \omega})^{\tilde{N}_c-1} = \\
& = \left\{ \exp \left[-\frac{i\pi}{6r\omega_1\omega_2} (\omega\Delta_X - \omega) \right] \right\}^{\tilde{N}_c-1} \Gamma_h(\omega\Delta_X; \omega_1, \omega_2)^{\tilde{N}_c-1}
\end{aligned} \tag{D.4}$$

$$\begin{aligned}
& \Gamma_e \left((pq)^{\frac{\Delta_X}{2}} \left(\frac{z_i}{z_j} \right) \right) \Gamma_e \left((pq)^{\frac{\Delta_X}{2}} \left(\frac{z_j}{z_i} \right) \right) = \\
& = \Gamma_e \left(\exp \left[2\pi i r \left(\frac{\Delta_X}{2} (\omega_1 + \omega_2) + (\sigma_i - \sigma_j) \right) \right] \right) \Gamma_e \left(\exp \left[2\pi i r \left(\frac{\Delta_X}{2} (\omega_1 + \omega_2) + (\sigma_j - \sigma_i) \right) \right] \right) = \\
& = \Gamma_e(\exp[2\pi i r(\Delta_X \omega + (\sigma_i - \sigma_j))]) \Gamma_e(\exp[2\pi i r(\Delta_X \omega + (\sigma_j - \sigma_i))]) \\
& = \exp \left(-\frac{i\pi}{6r\omega_1\omega_2} (2\omega\Delta_X + (\sigma_i - \sigma_j) + (\sigma_j - \sigma_i) - 2\omega) \right) \Gamma_h(\Delta_X \omega + \sigma_i - \sigma_j) \Gamma_h(\Delta_X \omega + \sigma_j - \sigma_i) \\
& = \exp \left(-\frac{i\pi}{6r\omega_1\omega_2} (2\omega(\Delta_X - 1)) \right) \Gamma_h(\Delta_X \omega + \sigma_i - \sigma_j) \Gamma_h(\Delta_X \omega + \sigma_j - \sigma_i)
\end{aligned} \tag{D.5}$$

Sum of the divergent contributions The exponent of the diverging terms is given by

$$\begin{aligned}
& \overbrace{(\omega(\Delta_x - 1)(\tilde{N}_c - 1) + (2\omega(\Delta_x - 1)\frac{\tilde{N}_c(\tilde{N}_c - 1)}{2}) + \omega(\tilde{N}_c^2 - 1))}^{\text{Adj Chiral}} + \overbrace{\omega(\tilde{N}_c^2 - 1)}^{\text{Vector}} + \\
& \overbrace{2N_f\tilde{N}_c\omega(\Delta' - 1) + \tilde{N}_c\left(\sum_{i=1}^{N_f} -m_i + \tilde{m}_i\right)}^{\text{Fond Chirals}} + \overbrace{N_f^2\left(\sum_{l=0}^{k-1} 2\omega(\Delta_Q + l\frac{\Delta_X}{2} - \frac{1}{2})\right) + N_f\left(\sum_{l=0}^{k-1} \sum_i^{N_f} m_i - \tilde{m}_i\right)}^{\text{Mesons}} = \\
& \tag{D.6}
\end{aligned}$$

In order to simplify this expression we need to use the following identity

$$\sum_{i=0}^n i = \frac{n(n+1)}{2} \quad \longrightarrow \quad \sum_{i=0}^{k-1} i = \frac{(k-1)k}{2} \tag{D.7}$$

which in the case of the meson becomes

$$N_f^2\omega(2\Delta_Q - 1)k + \omega\Delta_X\frac{(k-1)k}{2} + kN_f\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) \tag{D.8}$$

The exponent is then

$$\begin{aligned}
& \omega(\tilde{N}_c^2 - 1) + (\omega(\Delta_X - 1)(\tilde{N}_c^2 - 1) + 2N_f\tilde{N}_c\omega(\Delta_q - 1) + \tilde{N}_c\left(\sum_{i=1}^{N_f} -m_i + \tilde{m}_i\right) + \\
& + N_f^2\left(\omega(2\Delta_Q - 1)k + \omega\Delta_X\frac{(k-1)k}{2}\right) + kN_f\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) = \\
& = \omega((kN_f - N_c)^2 - 1) + (\omega(\Delta_X - 1)((kN_f - N_c)^2 - 1) + \\
& 2N_f(kN_f - N_c)\omega(\Delta_q - 1) + (kN_f - N_c)\left(\sum_{i=1}^{N_f} -m_i + \tilde{m}_i\right) + \\
& + N_f^2\left(\omega(2\Delta_Q - 1)k + \omega\Delta_X\frac{(k-1)k}{2}\right) + kN_f\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) \\
& \tag{D.9}
\end{aligned}$$

Using the explicit value of the R-charge for the dual quark ($\Delta_q = \Delta_X - \Delta_Q$) and the explicit value of Δ_X we obtain

$$\begin{aligned}
& \omega\Delta_x(N_c^2 - 1) + \omega(-2N_fN_c) + \omega\Delta_Q(2N_fN_c) + N_c\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) = \\
& = \omega\Delta_x(N_c^2 - 1) + (+\omega - \omega)(N_c^2 - 1) + 2N_fN_c\omega(\Delta_Q - 1) + N_c\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) = \\
& = \omega(N_c^2 - 1) + (N_c^2 - 1)\omega(\Delta_x - 1) + 2N_fN_c\omega(\Delta_Q - 1) + N_c\left(\sum_i^{N_f} m_i - \tilde{m}_i\right) \\
& \tag{D.10}
\end{aligned}$$

which coincides with the factor calculated in the electric theory.

D.2 Infinite mass limit

The divergent contribution in the limit $m \rightarrow \infty$ is given by

$$\begin{aligned}
& \text{Mesons} \left\{ \sum_{j=0}^{k-1} 4N_f m (-m_A(N_f - 1) + \omega(\Delta_Q + \Delta_M + j\Delta_X - 1)) + \right. \\
& \text{Chiral 1} \left\{ \begin{aligned} & +4(kN_f - N_c) \left(m_B \frac{N_c}{k(N_f+1)-N_c} (-m_A N_f - \omega(\Delta_X - \Delta_M - 1)) + \right. \\ & + m(m_A N_f + \omega(\Delta_X - \Delta_M - 1)) + \\ & \left. +4 \sum_j^{kN_f - N_c} \tilde{\sigma}_j (-m_A N_f - \omega(\Delta_X - \Delta_M - 1)) \right) \end{aligned} \right. \\
& \text{Chiral 2} \left\{ \begin{aligned} & +4kN_f \left(m_B \frac{N_c}{k(N_f+1)-N_c} (-m_A + \omega(\Delta_X - \Delta_Q - 1)) + \right. \\ & + m(-m_A + \omega(\Delta_X - \Delta_Q - 1)) + \\ & \left. +4N_f \sum_{j=1}^k \rho_j (-m_A + \omega(\Delta_X - \Delta_Q - 1)) \right) \end{aligned} \right. \\
& \text{Adj matter} \left\{ \begin{aligned} & +m(4\omega\Delta_X k(kN_f - N_C) + \\ & -4k \sum_i \tilde{\sigma}_i(\omega\Delta_X) + \\ & +4(kN_f - N_c) \sum_i \rho_i(\omega\Delta_X) \end{aligned} \right.
\end{aligned} \tag{D.11}$$

Let us simplify this expression by separating it into various terms

Contributions proportional to m They are given by

$$\begin{aligned}
& m \left(-4kN_f m_A(N_f - 1) - 4N_f N_c m_A + 4kN_f m m_A(N_f - 1) \right) + \\
& 4m\omega \left(kN_f(\Delta_Q + \Delta_M - 1) + \frac{(k-1)}{2} \Delta_X \right) + (kN_f - N_c)(\Delta_X - \Delta_M - 1) + kN_f(\Delta_X - \Delta_Q - 1) + \\
& + \Delta_X k(kN_f - N_C) \Big)
\end{aligned} \tag{D.12}$$

Using the constraint on the real masses we obtain

$$\omega(-N_c\Delta_X + N_f + 1) = \omega(N_f\Delta_Q + \Delta_M) \quad \rightarrow \quad \Delta_M = -N_c\Delta_X + N_f(1 - \Delta_Q) + 1 \tag{D.13}$$

Using the explicit value of Δ_X and writing $\frac{k-1}{2} = \frac{k+1}{2} - 1$

$$\begin{aligned}
& 4m \left(-N_f N_c m_A + \omega \left(kN_f(\Delta_Q - N_c\Delta_X + N_f(1 - \Delta_Q) + 1) + \frac{k+1}{2} \Delta_X - \Delta_X - 1 \right) + \right. \\
& + (kN_f - N_c)(\Delta_X - (-N_c\Delta_X + N_f(1 - \Delta_Q) + 1) - 1) + kN_f(\Delta_X - \Delta_Q - 1) \Big) + \\
& + \Delta_X k(kN_f - N_C) \Big)
\end{aligned} \tag{D.14}$$

which leads to

$$\begin{aligned}
& 4m\omega N_c (-N_f m_A - \Delta_X N_c - (\Delta_Q - 1)N_f) + \\
& + 4m\omega(kN_f - N_c)((\Delta_X - 2 + k\Delta_X)) = \\
& = 4m\omega N_c (-N_f m_A - \Delta_X N_c - (\Delta_Q - 1)N_f) + \\
& + 4m\omega(kN_f - N_c)(\Delta_X(k+1) - 2) = \\
& = 4m\omega N_c (-N_f m_A + (1 - \Delta_Q)N_f - \Delta_X N_c)
\end{aligned} \tag{D.15}$$

which match with the result from the electric theory.

Contributions proportional to m_B They are given by

$$\begin{aligned}
& 4m_B \frac{N_c}{k(N_f + 1) - N_c} \left((kN_f - N_c)(-m_A N_f - \omega(\Delta_X - \Delta_M - 1) + \right. \\
& \quad \left. + kN_f(-m_A + \omega(\Delta_X - \Delta_Q - 1))) = \right. \\
& = 4m_B \frac{N_c}{k(N_f + 1) - N_c} \left(kN_f(-m_A(N_f + 1) + \omega(\Delta_M - \Delta_Q)) + \right. \\
& \quad \left. - N_c(-m_A N_f - \omega(\Delta_X - \Delta_M - 1)) \right) = \\
& = 4m_B \frac{N_c}{k(N_f + 1) - N_c} \left(kN_f(-m_A(N_f + 1) + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q) + 1 - \Delta_Q)) + \right. \\
& \quad \left. + N_c(m_A N_f + \omega(\Delta_X - (-N_c \Delta_X + N_f(1 - \Delta_Q) + 1) - 1)) \right) = \\
& = 4m_B \frac{N_c}{k(N_f + 1) - N_c} \left(kN_f(-m_A(N_f + 1) + \omega(-N_c \Delta_X + N_f - (N_f + 1)\Delta_Q) + 1)) + \right. \\
& \quad \left. + m_A N_f N_c + N_c \omega(\Delta_X(N_c + 1) + N_f(\Delta_Q - 1) - 2) \right)
\end{aligned} \tag{D.16}$$

Simplifying some fractions we get

$$\begin{aligned}
& 4m_B N_c N_f (-m_A) + 4m_B N_c N_f (-\omega \Delta_Q) + 4m_B N_c^2 \omega \Delta_X \left(-1 + \frac{k+1}{k(N_f + 1) - N_c} \right) \\
& + 4m_B N_c N_f - 8m_B N_c^2 \omega \frac{1}{k(N_f + 1) - N_c}
\end{aligned} \tag{D.17}$$

Expliciting the value of Δ_X we obtain

$$4m_B N_c (-m_A N_f + \omega(N_f(1 - \Delta_Q) - N_c \Delta_X)) + 4m_B N_c^2 \omega \frac{1}{k(N_f + 1) - N_c} \left(\frac{2}{k+1}(k+1) - 2 \right) \tag{D.18}$$

which is the same as the contribution in the electric theory

$$4m_B N_c (-m_A N_f + \omega(N_f(1 - \Delta_Q) - N_c \Delta_X)) \tag{D.19}$$

Contributions proportional to $\sum_i \sigma_i + \sum_j \rho_j$ They are given by

$$\begin{aligned}
& 4 \sum_j^{kN_f - N_c} \tilde{\sigma}_j \left(-m_A N_f - \omega(\Delta_X(1+k) - \Delta_M - 1) \right) + \\
& 4N_f \sum_{j=1}^k \rho_j (-m_A + \omega(\Delta_X - \Delta_Q - 1)) + 4(kN_f - N_c) \sum_i \rho_i (\omega \Delta_X) = \\
& = 4 \sum_j^{kN_f - N_c} \tilde{\sigma}_j \left(-m_A N_f - \omega(1 - \Delta_M) \right) + \\
& + 4 \sum_{j=1}^k \rho_j (-m_A N_f + \omega(\Delta_X(N_f + (kN_f - N_c)) - N_f \Delta_Q - N_f)) = \\
& = 4 \sum_j^{kN_f - N_c} \tilde{\sigma}_j \left(-m_A N_f + \omega(\Delta_M - 1) \right) + \tag{D.20} \\
& + 4 \sum_{j=1}^k \rho_j (-m_A N_f + \omega(\Delta_X N_f(k+1) - N_c \Delta_X) - N_f \Delta_Q - N_f) = \\
& = 4 \sum_j^{kN_f - N_c} \tilde{\sigma}_j \left(-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q)) \right) + + \\
& + 4 \sum_{j=1}^k \rho_j (-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q))) = \\
& = 4 \left(\sum_i^{kN_f - N_c} \sigma_i + \sum_j^k \rho_j \right) (-m_A N_f + \omega(-N_c \Delta_X + N_f(1 - \Delta_Q)))
\end{aligned}$$

Acknowledgements

I want thank my supervisors for the efforts they put in this work.

In particular, I want to express my gratitude to Silvia Penati, who gave me the possibility to choose topic I was passionate about even though I was not sure about my scientific interests at the beginning. I thank her for the constant support she provided.

I can't express how grateful I am towards Antonio Amariti, who leaded me in this journey and has been always present for a Skype call when I needed help. I will always admire your deep passion for physics and the constancy you put in your work. I can not thank you enough.

I thank the university and the department of Physics for making this Master possible.
